

Estimation of exponential sums of polynomials of higher degrees II

by

YANGBO YE (Iowa City, IA)

1. Introduction. In Ye [10] the author proved the following bounds for an exponential sum. Let p be an odd prime and let b and c be integers relatively prime to p . Set $q = p^a$, $a \geq 1$, and $k \geq 0$. Define the exponential sum

$$S_k(q, b, c) = \sum_{x \bmod q} e\left(\frac{bx + cx^k}{q}\right)$$

where $e(x) = e^{2\pi ix}$. Then for $1 < m < p$ we have [10]

$$|S_{\phi(q)-m}(q, b, c)| \leq \begin{cases} (m+1)p^{1/2} + 1 & \text{if } m > 1, m \mid (p-1), \text{ and } a = 1, \\ (m+1)q^{1/2} & \text{if } 1 < m < p-1 \text{ and } a \geq 2, \\ p^{1/2}q^{1/2} & \text{if } m = p-1 \text{ and } a \geq 5, \\ pq^{1/2} & \text{if } m = p-1 \text{ and } a = 4, \\ p^{1/2}q^{1/2} & \text{if } m = p-1 \text{ and } a = 3, \\ q^{1/2} & \text{if } m = p-1 \text{ and } a = 2. \end{cases}$$

In this article we will prove certain identities between the above exponential sum and hyper-Kloosterman sums, generalize the above estimation for the exponential sum to other cases of m when $a \geq 2$, and establish new bounds for hyper-Kloosterman sums. Write $p^h \parallel n$ if $p^h \mid n$ but $p^{h+1} \nmid n$.

THEOREM 1. *Let p be a prime, $q = p^a$, $a \geq 2$, and k an integer with $a \leq k < \phi(q)$ and $p \nmid k$. We set h by $p^h \parallel (k-1)$. Then for any b and c relatively prime to p we have*

$$|S_k(q, b, c)| \leq \begin{cases} (\phi(q) - k + 1)q^{1/2} & \text{if } p \nmid (k-1), \\ (\phi(q) - k + 1)p^{-h/2}q^{1/2} & \text{if } h \geq 1 \text{ and } a \geq 3h+2, \\ (k-1, p-1)p^{\min(h, a/2-1)}q^{1/2} & \text{if } h \geq 1 \text{ and } 2 \mid a, \\ (k-1, p-1)p^{\min(h+1/2, a/2-1)}q^{1/2} & \text{if } h \geq 1 \text{ and } 2 \nmid a, \end{cases}$$

when $p > 2$, and

$$|S_k(q, b, c)| \leq \begin{cases} (\phi(q) - k + 1)p^{1-h/2}q^{1/2} & \text{if } h \geq 1 \text{ and } a \geq 3h + 5, \\ p^{\min(h+1, a/2-1)}q^{1/2} & \text{if } h \geq 1 \text{ and } 2 \mid a, \\ p^{\min(h+3/2, a/2-1)}q^{1/2} & \text{if } h \geq 1 \text{ and } 2 \nmid a, \end{cases}$$

when $p = 2$.

When $a \geq 3h+2$ with $p > 2$ and when $a \geq 3h+5$ with $p = 2$, two bounds are given in Theorem 1; the smaller bound applies. Loxton and Smith [5] proved that

$$|S_k(q, b, c)| \leq q^{1/2}d_{k-1}(q)(\Delta, q)^{1/2}$$

when b and c are relatively prime to p , where $d_{k-1}(q)$ is the number of representations of q as a product of $k - 1$ positive integers and Δ is the discriminant of the derivative of the polynomial $bx + cx^k$. After an improvement by Loxton and Vaughan [6], Dąbrowski and Fisher established in [1] better bounds for exponential sums of this kind. Under the restriction of $p \nmid k$, which is the case we will deal with in this paper, their Theorem 1.8 implies the following estimates (see Section 4 for details).

THEOREM 2. *Let p be a prime, $a \geq 2$, $q = p^a$, $k \geq 2$, $p \nmid k$, and $p^h \parallel (k-1)$. Then for any integers b and c relatively prime to p we have*

$$|S_k(q, b, c)| \leq \begin{cases} (k-1)q^{1/2} & \text{if } p \nmid (k-1) \text{ and } a \geq 2, \\ (k-1)p^{-h/2}q^{1/2} & \text{if } h \geq 1 \text{ and } a \geq 3h + 2, \\ (k-1, p-1)p^{\min(h, a/2-1)}q^{1/2} & \text{if } h \geq 1 \text{ and } 2 \mid a, \\ (k-1, p-1)p^{\min(h+1/2, a/2-1)}q^{1/2} & \text{if } h \geq 1 \text{ and } 2 \nmid a, \end{cases}$$

when $p > 2$, and

$$|S_k(q, b, c)| \leq \begin{cases} (k-1)p^{1-h/2}q^{1/2} & \text{if } h \geq 1 \text{ and } a \geq 3h + 5, \\ p^{\min(h+1, a/2-1)}q^{1/2} & \text{if } h \geq 1 \text{ and } 2 \mid a, \\ p^{\min(h+1/2, a/2-1)}q^{1/2} & \text{if } h \geq 1 \text{ and } 2 \nmid a, \end{cases}$$

when $p = 2$.

We note that the last two cases here for $p > 2$ and for $p = 2$ are the same as in Theorem 1. In other cases Theorem 1 is effective for large k while Theorem 2 gives better bounds for small k . In particular when $p > 2$ and $p \nmid k(k-1)$, we can combine these two theorems and get

$$|S_k(q, b, c)| \leq \min(k-1, \phi(q) - k + 1)q^{1/2}.$$

This estimate becomes worse than trivial when $q^{1/2} \leq k \leq \phi(q) - q^{1/2}$. What kind of non-trivial bounds one can get for k in this middle range is indeed an interesting question. See Vaughan [8] for a history of estimation of this exponential sum. The question of estimating this exponential sum for large k was posed by Loxton and Vaughan [6].

As in [10] our proof of Theorem 1 is based on certain identities between the above exponential sum and hyper-Kloosterman sums (Theorem 3). These identities are in turn deduced from generalized Davenport–Hasse identities of Gauss sums (Theorem 5). Using the new bounds for hyper-Kloosterman sums for prime power moduli obtained by Dąbrowski and Fisher [1] (see (19), (20), and an improved version in (1) and (2)), we then prove Theorem 1.

We denote a hyper-Kloosterman sum by

$$K(q, m + 1, z) = \sum_{\substack{x_1, \dots, x_m \pmod q \\ (x_1, p) = \dots = (x_m, p) = 1}} e\left(\frac{x_1 + \dots + x_m + z\bar{x}_1 \dots \bar{x}_m}{q}\right)$$

for $q = p^a$, $m \geq 1$, and $p \nmid z$. Define an exponential sum by

$$I(q, m, z) = \sum_{\substack{x \pmod q \\ (x, p) = 1}} e\left(\frac{mx + z\bar{x}^m}{q}\right).$$

The identities for hyper-Kloosterman sums are given in the following theorem. Set $\varepsilon_p = 1$ if $p \equiv 1 \pmod 4$, and $\varepsilon_p = i$ if $p \equiv 3 \pmod 4$.

THEOREM 3. *Let p be a prime, $m \geq 1$, $p \nmid m$, $a \geq 2$, and $q = p^a$. Then for any integer z with $p \nmid z$ we have*

$$K(q, m + 1, z) = \begin{cases} q^{(m-1)/2} I(q, m, z) & \text{if } 2 \mid a, \\ q^{(m-1)/2} \varepsilon_p^{m-1} \left(\frac{2^{m-1} z^{m-1} m}{p}\right) I(q, m, z) & \text{if } 2 \nmid a, \end{cases}$$

when $p > 2$, and

$$K(q, m + 1, z) = q^{(m-1)/2} \left(\frac{2}{m}\right)^a I(q, m, z)$$

when $p = 2$.

For the case of even a these identities were proved by Smith [7]. When $a = 1$ a similar identity is indeed the Diophantine manifestation of a geometric isomorphism of sheaves in Katz [4], Theorem 9.2.3. In Section 3 we will thus only consider the case of odd $a \geq 3$.

To see another application of our identities, we note that for any positive integer n ,

$$\begin{aligned} I(q, m + n\phi(q), z) &= \sum_{\substack{x \pmod q \\ (x, p) = 1}} e\left(\frac{(m + n\phi(q))x + z\bar{x}^{m+n\phi(q)}}{q}\right) \\ &= \sum_{\substack{y \pmod q \\ (y, p) = 1}} e\left(\frac{my + z(m + n\phi(q))^m \bar{m}^m \bar{y}^m}{q}\right) \end{aligned}$$

where we set $y \equiv (m + n\phi(q))\bar{m}x \pmod{q}$, which is still relatively prime to p because $p \nmid m$, $a \geq 2$, and $p \mid \phi(q)$. Since $(m + n\phi(q))^m \bar{m}^m \equiv 1 - np^{a-1} \pmod{q}$, we have

$$I(q, m + n\phi(q), z) = I(q, m, z(1 - np^{a-1})).$$

Applying this identity to the exponential sums on the right side in Theorem 3, we can easily deduce the following identity for hyper-Kloosterman sums.

COROLLARY. *Let p be any prime, m and n any positive integer, $p \nmid m$, $a \geq 2$, and $q = p^a$. Then for any integer z relatively prime to p we have*

$$K(q, m + n\phi(q) + 1, z) = \begin{cases} q^{n\phi(q)/2} K(q, m + 1, z(1 - np^{a-1})) & \text{if } 2 \mid a \text{ or if } p = 2, a \geq 5, \text{ and } 2 \nmid a, \\ q^{n\phi(q)/2} \varepsilon_p^{n\phi(q)} K(q, m + 1, z(1 - np^{a-1})) & \text{if } p > 2 \text{ and } 2 \nmid a. \end{cases}$$

This Corollary simplifies hyper-Kloosterman sums of prime power moduli with larger m , $p \nmid m$, to hyper-Kloosterman sums with m between 1 and $\phi(q) - 1$. Consequently, the bounds for hyper-Kloosterman sums of prime power moduli proved by Dąbrowski and Fisher [1] (see (19) and (20) in Section 4) can be rewritten and improved for large m when $p \nmid m$. These improved bounds may also be proved directly following their Theorem 1.8 and Example 1.17:

$$(1) \quad |K(q, m + 1, z)| \leq \begin{cases} (r + 1)q^{m/2} & \text{if } p \nmid (r + 1), \\ (r + 1)p^{-h/2}q^{m/2} & \text{if } h \geq 1 \text{ and } a \geq 3h + 2, \\ (r + 1, p - 1)p^{\min(h, a/2-1)}q^{m/2} & \text{if } h \geq 1 \text{ and } 2 \mid a, \\ (r + 1, p - 1)p^{\min(h+1/2, a/2-1)}q^{m/2} & \text{if } h \geq 1 \text{ and } 2 \nmid a, \end{cases}$$

when $p > 2$, and

$$(2) \quad |K(q, m + 1, z)| \leq \begin{cases} (r + 1)p^{1-h/2}q^{m/2} & \text{if } h \geq 1 \text{ and } a \geq 3h + 5, \\ p^{\min(h+1, a/2-1)}q^{m/2} & \text{if } h \geq 1 \text{ and } 2 \mid a, \\ p^{\min(h+3/2, a/2-1)}q^{m/2} & \text{if } h \geq 1 \text{ and } 2 \nmid a, \end{cases}$$

when $p = 2$, where h is given by $p^h \parallel (r + 1)$ and $m \equiv r \pmod{\phi(q)}$ with $1 \leq r < \phi(q)$ and $p \nmid r$.

Using the Corollary and the identities in Theorem 3 backward, we can further deduce new bounds for hyper-Kloosterman sums from the bounds for the exponential sum $S_k(q, b, c)$. These new bounds are sharper than the improved bounds of Dąbrowski and Fisher in (1) and (2) when $m \equiv r \pmod{\phi(q)}$ with r being less than and close to $\phi(q) - a$. Here in order to

have

$$\sum_{\substack{x \pmod q \\ p \nmid x}} e\left(\frac{bx + cx^{\phi(q)-r}}{q}\right) = 0$$

we need to assume that $\phi(q) - r \geq a$.

THEOREM 4. *Let p be any prime. Assume that $a \geq 2$ when $p > 2$ and $a \geq 4$ when $p = 2$. Set $q = p^a$ and let m be any positive integer with $p \nmid m$, $m \equiv r \pmod{\phi(q)}$ and $1 \leq r \leq \phi(q) - a$. Define h by $p^h \parallel (r + 1)$. Then for any integer z relatively prime to p we have*

$$|K(q, m + 1, z)| \leq \begin{cases} (\phi(q) - r - 1)q^{m/2} & \text{if } p \nmid (r + 1), \\ (\phi(q) - r - 1)p^{-h/2}q^{m/2} & \text{if } h \geq 1 \text{ and } a \geq 3h + 2, \\ (r + 1, p - 1)p^{\min(h, a/2-1)}q^{m/2} & \text{if } h \geq 1 \text{ and } 2 \mid a, \\ (r + 1, p - 1)p^{\min(h+1/2, a/2-1)}q^{m/2} & \text{if } h \geq 1 \text{ and } 2 \nmid a, \end{cases}$$

when $p > 2$, and

$$|K(q, m + 1, z)| \leq \begin{cases} (\phi(q) - r - 1)p^{1-h/2}q^{m/2} & \text{if } h \geq 1 \text{ and } a \geq 3h + 5, \\ p^{\min(h+1, a/2-1)}q^{m/2} & \text{if } h \geq 1 \text{ and } 2 \mid a, \\ p^{\min(h+3/2, a/2-1)}q^{m/2} & \text{if } h \geq 1 \text{ and } 2 \nmid a, \end{cases}$$

when $p = 2$.

Estimation of hyper-Kloosterman sums for prime moduli was proved by Deligne [2] and Katz [3]. It is interesting to see whether bounds like those in Theorem 4 can be established for hyper-Kloosterman sums modulo p .

2. New Davenport–Hasse identities for Gauss sums. Let p be a prime and $m > 1$ an integer with $p \nmid m$. Let χ be any ramified multiplicative character on the p -adic field \mathbb{Q}_p with conductor exponent $a(\chi) = a$. Here χ is ramified if it is non-trivial on R_p^\times , the group of invertible elements of the ring of integers R_p in \mathbb{Q}_p ; for a ramified multiplicative character χ its conductor exponent, denoted by $a(\chi)$, is the smallest positive integer a such that χ is trivial on $1 + p^a R_p$. Let ψ be an additive character of \mathbb{Q}_p whose order is zero. Here the order of an additive character ψ , denoted by $n(\psi)$, is the largest integer n such that the character ψ is trivial on $p^{-n} R_p$.

For any additive character ϕ we define the *local ε -factor* as

$$\varepsilon(\chi, \phi; dx) = \begin{cases} \chi(p^{n(\phi)})p^{n(\phi)} & \text{if } \chi \text{ is unramified,} \\ \int_{p^{-a(\chi)-n(\phi)} R_p^\times} \chi^{-1}(x)\phi(x) dx & \text{if } \chi \text{ is ramified,} \end{cases}$$

where dx is a Haar measure on \mathbb{Q}_p normalized by $\text{volume}(R_p) = 1$. Then the new Davenport–Hasse identities for Gauss sums have the following form.

THEOREM 5. *Let p be a prime and $m > 1$ an integer with $p \nmid m$. Let ψ be a non-trivial additive character of \mathbb{Q}_p of order zero. Then for any ramified multiplicative character χ with conductor exponent $a(\chi) = a \geq 2$ we have*

$$(\varepsilon(\chi, \psi; dx))^m = \begin{cases} q^{(m-1)/2} \chi^m(m) \varepsilon(\chi^m, \psi; dx) & \text{if } 2 \mid a, \\ q^{m-1-[m/p]} \chi^m(m) \varepsilon(\chi^m, \psi; dx) \\ \times \prod_{\substack{2 \leq j \leq m \\ p \nmid j(j-1)}} \int_{p^{(a-1)/2} R_p} \chi \left(1 + \frac{j-1}{2j} y_j^2 \right) dy_j & \text{if } 2 \nmid a, \end{cases}$$

when $p > 2$, and

$$(\varepsilon(\chi, \psi; dx))^m = \begin{cases} q^{(m-1)/2} \chi^m(m) \varepsilon(\chi^m, \psi; dx) & \text{if } 2 \mid a, \\ q^{m-1-[(m-1)/4]} \chi^m(m) \varepsilon(\chi^m, \psi; dx) \\ \times \left(\int_{u,v \in p^{(a-1)/2} R_p} \chi(1 + u^2 + uv + v^2) du dv \right)^{[(m+1)/4]} & \text{if } 2 \nmid a, \end{cases}$$

when $p = 2$, where $q = p^a$.

Proof. Following the computation in Ye [9] and [10] we have

$$(\varepsilon(\chi, \psi; dx))^m = \int_{(q^{-1} R_p^\times)^m} \chi^{-1}(x_1 \dots x_m) \psi(x_1 + \dots + x_m) dx_1 \dots dx_m.$$

Change variables from x_i to $y_i = x_i/x_1$ for $i = 2, \dots, m$. Since $p \nmid m$, the conductor exponent of χ^m is still a . Consequently, the integral with respect to x_1 vanishes unless $1 + y_2 + \dots + y_m \in R_p^\times$. Setting $z = x_1(1 + y_2 + \dots + y_m)$ we get

$$(\varepsilon(\chi, \psi; dx))^m = q^{m-1} \varepsilon(\chi^m, \psi; dx) \times \int_{\substack{y_2, \dots, y_m \in R_p^\times \\ 1+y_2+\dots+y_m \in R_p^\times}} \chi \left(\frac{(1 + y_2 + \dots + y_m)^m}{y_2 \dots y_m} \right) dy_2 \dots dy_m.$$

Denote the integral by I_m . Since $a(\chi) = a \geq 2$, for $m \geq 3$ we set $y_m = y_0(1 + u)$ where

$$y_0 \in (R_p^\times - (-(1 + y_2 + \dots + y_{m-1}) + pR_p)) / (1 + p^{[(a+1)/2]} R_p)$$

and $u \in p^{[(a+1)/2]} R_p$. The integral with respect to u vanishes unless $1 + y_2 + \dots + y_{m-1} - (m-1)y_0 \in p^{[a/2]} R_p$. Therefore the variables in I_m satisfy

$$(3) \quad 1 + y_2 + \dots + y_{m-1} - (m-1)y_m \in p^{[a/2]} R_p.$$

If $p \nmid (m-1)$, then we get the case discussed in [10]. Setting $y_m = (1 + y_2 + \dots + y_{m-1}) / (m-1) + y$ with $y \in p^{[a/2]}R_p$ we get

$$(4) \quad I_m = I_{m-1} \chi \left(\frac{m^m}{(m-1)^{m-1}} \right) \int_{p^{[a/2]}R_p} \chi \left(1 + \frac{(m-1)y^2}{2m} \right) dy$$

when $p > 2$, $m \geq 3$, and $p \nmid m(m-1)$. When a is even, we can further compute the integral in (4) to get

$$(5) \quad I_m = q^{-1/2} \chi \left(\frac{m^m}{(m-1)^{m-1}} \right) I_{m-1}$$

when $p > 2$, $m \geq 3$, $p \nmid m(m-1)$, and $2 \mid a$.

Now we consider the case of $p \mid (m-1)$ and $m \geq 4$. Then from (3) we know that $1 + y_2 + \dots + y_{m-1} \in pR_p$; hence $1 + y_2 + \dots + y_{m-2} \in R_p^\times$ and $y_{m-1} \in -(1 + y_2 + \dots + y_{m-2}) + (m-1)y_m + p^{[a/2]}R_p$. Set $y_{m-1} = -(1 + y_2 + \dots + y_{m-2}) + (m-1)y_m + y$ with $y \in p^{[a/2]}R_p$. Then

$$(6) \quad I_m = \int_{\substack{y \in p^{[a/2]}R_p \\ y_2, \dots, y_{m-2}, y_m \in R_p^\times \\ 1 + y_2 + \dots + y_{m-2} \in R_p^\times}} \chi \left(-\frac{(my_m + y)^m}{y_2 \dots y_{m-2} y_m (1 + y_2 + \dots + y_{m-2} - (m-1)y_m - y)} \right) \times dy dy_2 \dots dy_{m-2} dy_m.$$

When $2 \mid a$, the integrand above equals

$$\chi \left(-\frac{m^m y_m^{m-1}}{y_2 \dots y_{m-2} (1 + y_2 + \dots + y_{m-2} - (m-1)y_m)} \right) \times \chi \left(1 + \left(\frac{1}{y_m} + \frac{1}{1 + y_2 + \dots + y_{m-2} - (m-1)y_m} \right) y \right).$$

Consequently, in order to have a non-zero integral with respect to y we must have

$$\frac{1}{y_m} + \frac{1}{1 + y_2 + \dots + y_{m-2} - (m-1)y_m} \in p^{a/2}R_p,$$

which is equivalent to $1 + y_2 + \dots + y_{m-2} - (m-2)y_m \in p^{a/2}R_p$. Note that $p \nmid (m-2)$; hence we can set $y_m = (1 + y_2 + \dots + y_{m-2}) / (m-2) + z$ with $z \in p^{a/2}R_p$. Integrating with respect to y and substituting the above expression of y_m into

$$\chi \left(-\frac{m^m y_m^{m-1}}{y_2 \dots y_{m-2} (1 + y_2 + \dots + y_{m-2} - (m-1)y_m)} \right)$$

we can see that the resulting expression is independent of z :

$$\chi\left(\frac{m^m}{(m-2)^{m-2}}\right)\chi\left(\frac{(1+y_2+\dots+y_{m-2})^{m-2}}{y_2\dots y_{m-2}}\right).$$

Integrating with respect to z we get

$$(7) \quad I_m = q^{-1}\chi\left(\frac{m^m}{(m-2)^{m-2}}\right)I_{m-2}$$

when $p > 2$, $m \geq 4$, $p \nmid m$, $p \mid (m-1)$, $a \geq 2$, and $2 \mid a$.

Now let us turn to the case of $2 \nmid a$. Then the integral in (6) becomes

$$(8) \quad I_m = \int_{\substack{y \in p^{(a-1)/2}R_p \\ y_2, \dots, y_{m-2}, y_m \in R_p^\times \\ 1+y_2+\dots+y_{m-2} \in R_p^\times}} \chi\left(-\frac{m^m y_m^{m-1}}{y_2 \dots y_{m-2} (1+y_2+\dots+y_{m-2}-(m-1)y_m)}\right) \\ \times \chi\left(1+y\left(\frac{1}{y_m} + \frac{1}{1+y_2+\dots+y_{m-2}-(m-1)y_m}\right)\right) \\ + y^2\left(\frac{m-1}{2my_m^2} + \frac{\frac{1}{y_m} + \frac{1}{1+y_2+\dots+y_{m-2}-(m-1)y_m}}{1+y_2+\dots+y_{m-2}-(m-1)y_m}\right) \\ \times dy dy_2 \dots dy_{m-2} dy_m.$$

Since we assume in this case that $p > 2$, the term $(m-1)/(2my_m^2) \in pR_p$ and hence can be taken out of the above integrand. Setting $y = z + u$ with $z \in p^{(a-1)/2}R_p/p^{(a+1)/2}R_p$ and $u \in p^{(a+1)/2}R_p$, we have $y^2 \in z^2 + qR_p$. Integrating with respect to u we get a non-zero result only if

$$\frac{1}{y_m} + \frac{1}{1+y_2+\dots+y_{m-2}-(m-1)y_m} \in p^{(a-1)/2}R_p.$$

Because of this condition, the integrand in (8) can be simplified to

$$\chi\left(-\frac{m^m y_m^{m-1}}{y_2 \dots y_{m-2} (1+y_2+\dots+y_{m-2}-(m-1)y_m)}\right) \\ \times \chi\left(1+y\left(\frac{1}{y_m} + \frac{1}{1+y_2+\dots+y_{m-2}-(m-1)y_m}\right)\right).$$

Then the integral with respect to y is non-zero only when

$$\frac{1}{y_m} + \frac{1}{1+y_2+\dots+y_{m-2}-(m-1)y_m} \in p^{(a+1)/2}R_p,$$

i.e., only when $1+y_2+\dots+y_{m-2}-(m-2)y_m \in p^{(a+1)/2}R_p$. Integrate with respect to y and set $y_m = (1+y_2+\dots+y_{m-2})/(m-2) + z$ with $z \in p^{(a+1)/2}R_p$. If we substitute this expression for y_m , we can see the

integrand is indeed independent of z . Integrating with respect to z as before we conclude that

$$(9) \quad I_m = q^{-1} \chi\left(\frac{m^m}{(m-2)^{m-2}}\right) I_{m-2}$$

when $p > 2$, $m \geq 4$, $p \nmid m$, $p \mid (m-1)$, $a \geq 2$, and $2 \nmid a$.

Using the same approach as above we can also get

$$(10) \quad I_2 = q^{-1/2} \chi(2^2)$$

when $p > 2$, $a \geq 2$, and $2 \mid a$, and

$$(11) \quad I_2 = \chi(2^2) \int_{p^{(a-1)/2} R_p} \chi\left(1 + \frac{y^2}{4}\right) dy$$

when $p > 2$, $a \geq 2$, and $2 \nmid a$. Putting all these results from (4), (5), (7), (9), (10), and (11) together we get the following expressions for I_m :

$$I_m = q^{(1-m)/2} \chi(m^m)$$

when $p > 2$, $m \geq 2$, $p \nmid m$, $a \geq 2$, and $2 \mid a$, and

$$I_m = q^{-[m/p]} \chi(m^m) \prod_{\substack{2 \leq j \leq m \\ p \nmid j(j-1)}} \int_{p^{(a-1)/2} R_p} \chi\left(1 + \frac{(j-1)y_j^2}{2j}\right) dy_j$$

when $p > 2$, $m \geq 2$, $p \nmid m$, $a \geq 2$, and $2 \nmid a$. Theorem 5 in the case of $p > 2$ then follows.

We now consider the case of $p = 2$. Following the same approach as above we set

$$I_m = \int_{\substack{y_2, \dots, y_m \in R_p^\times \\ 1+y_2+\dots+y_m \in R_p^\times}} \chi\left(\frac{(1+y_2+\dots+y_m)^m}{y_2 \dots y_m}\right) dy_2 \dots dy_m$$

so that

$$(\varepsilon(\chi, \psi; dx))^m = q^{m-1} \varepsilon(\chi^m, \psi; dx) I_m.$$

Since $p = 2$ and $2 \nmid m$, we always have $p \mid (m-1)$. For $m \geq 5$ we get the same expression of I_m as in (6) which implies (7) when a is even. When a is odd, we get (8) again. If $4 \mid (m-1)$, then we still have $(m-1)/(2my_m^2) \in pR_p$ and hence this term can be taken out of the integrand in (8). By the same computation, we get (9). Therefore

$$(12) \quad I_m = q^{-1} \chi\left(\frac{m^m}{(m-2)^{m-2}}\right) I_{m-2}$$

when (i) $p = 2$, $m \geq 5$, $2 \nmid m$, $a \geq 2$, and $2 \mid a$, or (ii) $p = 2$, $m \geq 5$, $2 \nmid m$, $4 \mid (m-1)$, $a \geq 3$, and $2 \nmid a$.

Now we consider the case of $p = 2$, $2 \nmid m$, $4 \nmid (m - 1)$, $a \geq 3$, and $2 \nmid a$. Then $(m - 1)/(2my_m^2) \in R_p^\times$. Consequently, by setting $y = z + u$ with $z \in p^{(a-1)/2}R_p/p^{(a+1)/2}R_p$ and $u \in p^{(a+1)/2}R_p$, we can only get

$$\frac{1}{y_m} + \frac{1}{1 + y_2 + \dots + y_{m-2} - (m - 1)y_m} \in p^{(a-1)/2}R_p.$$

Set $y_m = (1 + y_2 + \dots + y_{m-2})/(m - 2) + z$ with $z \in p^{(a-1)/2}R_p$. Then (8) can be simplified to

$$I_m = \int_{\substack{y, z \in p^{(a-1)/2}R_p \\ y_2, \dots, y_{m-2} \in R_p^\times \\ 1 + y_2 + \dots + y_{m-2} \in R_p^\times}} \chi\left(\frac{m^m}{(m - 2)^{m-2}}\right) \chi\left(\frac{(1 + y_2 + \dots + y_{m-2})^{m-2}}{y_2 \dots y_{m-2}}\right) \\ \times \chi\left(1 + \frac{(m - 1)z^2}{2(m - 2)}\right) \chi\left(1 - yz + \frac{(m - 1)y^2}{2m}\right) dy dz dy_2 \dots dy_{m-2}.$$

Since $(m - 1)/2$ is an odd integer we can further simplify the integrals with respect to y and z to get

$$(13) \quad I_m = \chi\left(\frac{m^m}{(m - 2)^{m-2}}\right) I_{m-2} \int_{y, z \in p^{(a-1)/2}R_p} \chi(1 + y^2 + yz + z^2) dy dz$$

when $p = 2$, $m \geq 5$, $2 \nmid m$, $4 \nmid (m - 1)$, $a \geq 3$, and $2 \nmid a$.

We can also compute I_3 :

$$(14) \quad I_3 = q^{-1} \chi(3^3)$$

if $p = 2$, $a \geq 2$, and $2 \mid a$, and

$$(15) \quad I_3 = \chi(3^3) \int_{u, v \in p^{(a-1)/2}R_p} \chi(1 + u^2 + uv + v^2) du dv$$

if $p = 2$, $a \geq 2$, and $2 \nmid a$. Putting the results in (12)–(15) together we prove Theorem 5 for $p = 2$.

3. Identities for hyper-Kloosterman sums. In this section we will prove Theorem 3 when $a \geq 3$ is odd. Denote the hyper-Kloosterman sum over p -adic field by

$$K_p(q, m + 1, z) = \sum_{x_1, \dots, x_m \in R_p^\times / (1 + qR_p)} \psi\left(\frac{1}{q} \left(x_1 + \dots + x_m + \frac{z}{x_1 \dots x_m}\right)\right).$$

Applying the Mellin transform to the p -adic hyper-Kloosterman sum as in [10], we get

$$\int_{R_p^\times} \chi^{-1}(z) K_p(q, m + 1, z) dz = q^{-1} \chi^{-(m+1)}(q) (\varepsilon(\chi, \psi; dx))^{m+1}$$

when $a(\chi) = a \geq 2$ and $q = p^a$. By Theorem 5 when p is odd and $p \nmid m$ the above becomes

$$q^{m-2-[m/p]} \chi^{-(m+1)}(q) \chi^m(m) \varepsilon(\chi, \psi; dx) \varepsilon(\chi^m, \psi; dx) \times \prod_{\substack{2 \leq j \leq m \\ p \nmid j(j-1)}} \int_{p^{(a-1)/2} R_p} \chi \left(1 + \frac{j-1}{2j} y_j^2 \right) dy_j$$

if a is odd. By the same computation as in [10] we can prove that

$$(16) \quad \int_{R_p^\times} \chi^{-1}(z) K_p(q, m+1, z) dz = q^{(m-1)/2} \varepsilon_p^{m-1-2[m/p]} \int_{R_p^\times} \chi^{-1}(z) dz \times \sum_{x \in R_p^\times / (1+qR_p)} \psi \left(\frac{1}{q} \left(mx + \frac{z}{x^m} \right) \right) \prod_{\substack{2 \leq j \leq m \\ p \nmid j(j-1)}} \left(\frac{2j(j-1)x^m z}{p} \right)$$

when $p > 2$, $p \nmid m$, $2 \nmid a$ for any multiplicative character χ . Since the number of factors in the product in (16) is $m - 1 - 2[m/p]$, the product equals

$$\left(\frac{x^m}{p} \right)^{m-1-2[m/p]} \left(\frac{z}{p} \right)^{m-1-2[m/p]} \prod_{\substack{2 \leq j \leq m \\ p \nmid j(j-1)}} \left(\frac{j(j-1)}{p} \right) = \left(\frac{x}{p} \right)^{m(m-1)} \left(\frac{2z}{p} \right)^{m-1} \left(\frac{m}{p} \right) \prod_{1 \leq k < m/p} \left(\frac{(kp+1)(kp-1)}{p} \right) = \left(\frac{2z}{p} \right)^{m-1} \left(\frac{m}{p} \right) \left(\frac{-1}{p} \right)^{[m/p]}.$$

Consequently, we proved the following identity over the p -adic field:

$$K_p(q, m+1, z) = q^{(m-1)/2} \varepsilon_p^{m-1} \left(\frac{2^{m-1} z^{m-1} m}{p} \right) \times \sum_{x \in R_p^\times / (1+qR_p)} \psi \left(\frac{1}{q} \left(mx + \frac{z}{x^m} \right) \right)$$

when $p > 2$, $p \nmid m$, $2 \nmid a$, and $p \nmid z$. This identity is equivalent to Theorem 3 in the case of odd p which is a generalization of a result proved in [10].

Now we turn to the case of $p = 2$ with $2 \nmid m$. When $a \geq 3$ is odd, we deduce from Theorem 5 that

$$\begin{aligned}
 (17) \quad & \int_{R_p^\times} \chi^{-1}(z) K_p(q, m+1, z) dz \\
 &= q^{m-2-[(m-1)/4]} \chi^{-(m+1)}(q) \chi^m(m) \varepsilon(\chi, \psi; dx) \varepsilon(\chi^m, \psi; dx) \\
 &\quad \times \left(\int_{u, v \in p^{(a-1)/2} R_p} \chi(1 + u^2 + uv + v^2) du dv \right)^{[(m+1)/4]}.
 \end{aligned}$$

We have

$$\begin{aligned}
 & q^{-2} \chi^{-(m+1)}(q) \varepsilon(\chi, \psi; dx) \varepsilon(\chi^m, \psi; dx) \\
 &= q^{-2} \chi^{-(m+1)}(q) \int_{(q^{-1} R_p^\times)^2} \chi^{-1}(x_1 x_2^m) \psi(x_1 + x_2) dx_1 dx_2 \\
 &= \int_{(R_p^\times)^2} \chi^{-1}(x) \psi\left(\frac{1}{q} \left(y + \frac{x}{y^m}\right)\right) dx dy.
 \end{aligned}$$

Rewriting the power in (17) as

$$\prod_{1 \leq j \leq [(m+1)/4]} \int_{u_j, v_j \in p^{(a-1)/2} R_p} \chi(1 + u_j^2 + u_j v_j + v_j^2) du_j dv_j$$

we then change variables from x to z via

$$x = z m^m \prod_{1 \leq j \leq [(m+1)/4]} (1 + u_j^2 + u_j v_j + v_j^2).$$

Then the expression on the right side of (17) becomes

$$\begin{aligned}
 & q^{m-[(m-1)/4]} \int_{(R_p^\times)^2} \chi^{-1}(z) dz dy \\
 & \times \int_{\substack{u_j, v_j \in p^{(a-1)/2} R_p \\ 1 \leq j \leq [(m+1)/4]}} \psi\left(\frac{1}{q} \left(y + \frac{z m^m}{y^m} \prod_{1 \leq j \leq [(m+1)/4]} (1 + u_j^2 + u_j v_j + v_j^2)\right)\right) \\
 & \quad \times dz dy du_1 dv_1 \dots du_{[(m+1)/4]} dv_{[(m+1)/4]}.
 \end{aligned}$$

Changing variables again and multiplying out the product we get

$$\begin{aligned}
 & q^{m-1-[(m-1)/4]} \int_{R_p^\times} \chi^{-1}(z) dz \sum_{y \in R_p^\times / (1+qR_p)} \psi\left(\frac{1}{q} \left(my + \frac{z}{y^m}\right)\right) \\
 & \quad \times \left(\int_{u, v \in p^{(a-1)/2} R_p} \psi\left(\frac{z}{qy^m} (u^2 + uv + v^2)\right) du dv \right)^{[(m+1)/4]}.
 \end{aligned}$$

In order to compute the integral with respect to u and v we write it as a

finite sum

$$\begin{aligned} & \int_{u,v \in p^{(a-1)/2}R_p} \psi\left(\frac{z}{qy^m}(u^2 + uv + v^2)\right) du dv \\ &= p^{-a-1} \sum_{u,v \in p^{(a-1)/2}R_p/p^{(a+1)/2}R_p} \psi\left(\frac{z}{qy^m}(u^2 + uv + v^2)\right) \\ &= p^{-a-1} \sum_{u,v \in R_p/pR_p} \psi\left(\frac{z}{py^m}(u^2 + uv + v^2)\right). \end{aligned}$$

Since $p = 2$, we can take $u, v = 0, 1$ and get

$$p^{-a-1} \left(1 + 2\psi\left(\frac{z}{py^m}\right) + \psi\left(\frac{3z}{py^m}\right) \right).$$

Since the order of ψ is zero and $p^{-1}R_p^\times/R_p$ has only one element, we have

$$\psi\left(\frac{z}{py^m}\right) = \psi\left(\frac{3z}{py^m}\right) = -1$$

and hence

$$\int_{u,v \in p^{(a-1)/2}R_p} \psi\left(\frac{z}{qy^m}(u^2 + uv + v^2)\right) du dv = -q^{-1}.$$

Consequently,

$$\begin{aligned} & \int_{R_p^\times} \chi^{-1}(z) K_p(q, m+1, z) dz \\ &= q^{(m-1)/2} \left(\frac{2}{m}\right) \int_{R_p^\times} \chi^{-1}(z) dz \sum_{y \in R_p^\times/(1+qR_p)} \psi\left(\frac{1}{q}\left(my + \frac{z}{y^m}\right)\right) \end{aligned}$$

for any ramified character χ with conductor exponent $a(\chi) = a$, where we used the facts that

$$[(m-1)/4] + [(m+1)/4] = (m-1)/2 \quad \text{and} \quad (-1)^{[(m+1)/4]} = \left(\frac{2}{m}\right).$$

Since $a > 1$ this identity also holds for other multiplicative character χ . Therefore we proved the following identity which is equivalent to Theorem 3 in the case of $p = 2$, $p \nmid m$, $a \geq 3$, and $2 \nmid a$:

$$(18) \quad K_p(q, m+1, z) = q^{(m-1)/2} \left(\frac{2}{m}\right) \sum_{y \in R_p^\times/(1+qR_p)} \psi\left(\frac{1}{q}\left(my + \frac{z}{y^m}\right)\right)$$

for any $z \in R_p^\times$.

4. Estimation of exponential sums. We first prove Theorem 2 using Theorem 1.8 of Dąbrowski and Fisher [1]. Let $f(x) = bx + cx^k$ be a polynomial with $b, c,$ and k relatively prime to p . For $a \geq 2$ we set $q = p^a$ and $j = \lceil a/2 \rceil$. Define the scheme D of critical points of f as zeros of $f'(x) = b + ckx^{k-1}$. Then a point x in D is *étale* if $p \nmid (k-1)$, x is *h -étale* if $p^h \parallel (k-1)$, and x is *strictly h -étale* if $p^{h+1} \parallel (k-1)$. Theorem 1.8(a) of Dąbrowski and Fisher [1] says that

$$|S_k(q, b, c)| \leq \begin{cases} |D(\mathbb{Z}/p^j\mathbb{Z})|q^{1/2} & \text{if } 2 \mid a \text{ or if } 2 \nmid a \text{ and } p \nmid (k-1), \\ |D(\mathbb{Z}/p^j\mathbb{Z})|p^{1/2}q^{1/2} & \text{if } 2 \nmid a \text{ and } p \mid (k-1). \end{cases}$$

Theorem 1.8(b) on the other hand implies that

$$|S_k(q, b, c)| \leq |D(\mathbb{Z}_p)|p^{h/2}q^{1/2}$$

if $a \geq 3h + 2$ when $p > 2$ or $a \geq 3h + 5$ when $p = 2$, where $h \geq 1$ is given by $p^h \parallel (k-1)$. Following Example 1.17 of [1] we have

$$|D(\mathbb{Z}/p^j\mathbb{Z})| \leq \begin{cases} k-1 & \text{if } p \nmid (k-1), \\ p^{\min(h+1, j-1)} & \text{if } p = 2 \text{ and } h \geq 1, \\ (k-1, p-1)p^{\min(h, j-1)} & \text{if } p > 2 \text{ and } h \geq 1, \end{cases}$$

and

$$|D(\mathbb{Z}_p)| \leq \begin{cases} (k-1)p^{-h} & \text{if } p > 2, \\ (k-1)p^{1-h} & \text{if } p = 2. \end{cases}$$

Substituting these results into the above inequalities for the exponential sum, we get the estimates in Theorem 2.

By similar computation the bounds for the hyper-Kloosterman sum $K(q, m+1, z)$ considered in Example 1.17 of Dąbrowski and Fisher [1] can be written in the following way. Here h is given by $p^h \parallel (m+1)$.

$$(19) \quad |K(q, m+1, z)| \leq \begin{cases} (m+1)q^{m/2} & \text{if } p \nmid (m+1), \\ (m+1)p^{-h/2}q^{m/2} & \text{if } h \geq 1 \text{ and } a \geq 3h+2, \\ (m+1, p-1)p^{\min(h, a/2-1)}q^{m/2} & \text{if } h \geq 1 \text{ and } 2 \mid a, \\ (m+1, p-1)p^{\min(h+1/2, a/2-1)}q^{m/2} & \text{if } h \geq 1 \text{ and } 2 \nmid a, \end{cases}$$

when $p > 2$, and

$$(20) \quad |K(q, m+1, z)| \leq \begin{cases} (m+1)p^{1-h/2}q^{m/2} & \text{if } h \geq 1 \text{ and } a \geq 3h+5, \\ p^{\min(h+1, a/2-1)}q^{m/2} & \text{if } h \geq 1 \text{ and } 2 \mid a, \\ p^{\min(h+3/2, a/2-1)}q^{m/2} & \text{if } h \geq 1 \text{ and } 2 \nmid a, \end{cases}$$

when $p = 2$. As before here we assume that $p \nmid m$. By the identities of hyper-Kloosterman sums in Theorem 3, we get the same bounds as in Theorem 1

but for the exponential sum

$$\sum_{\substack{x \bmod q \\ (x,p)=1}} e\left(\frac{mx + z\bar{x}^m}{q}\right)$$

if we set $k = \phi(q) - m$. For m in the range of $1 \leq m \leq \phi(q) - a$, however

$$\sum_{\substack{x \bmod q \\ p \mid x}} e\left(\frac{mx + zx^{\phi(q)-m}}{q}\right) = 0.$$

This completes the proof of Theorem 1.

Acknowledgements. The author would like to thank the referee for helpful suggestions.
