In this paper, a singularly perturbed system of reaction–diffusion Boundary Value Problems (BVPs) is examined. To solve such a type of problems, a Modified Initial Value Technique (MIVT) is proposed on an appropriate piecewise uniform Shishkin mesh. The MIVT is shown to be of second order convergent (up to a logarithmic factor). Numerical results are presented which are in agreement with the theoretical results.

Keywords: asymptotic expansion approximation, backward difference operator, trapezoidal method, piecewise uniform Shishkin mesh.

1. Introduction

In many fields of applied mathematics we often come across initial/boundary value problems with small positive parameters. If, in a problem arising in this manner, the role of the perturbation is played by the leading terms of the differential operator (or part of them), then the problem is called a Singularly Perturbed Problem (SPP). Applications of SPPs include boundary layer problems, WKB theory, the modeling of steady and unsteady viscous flow problems with a large Reynolds number and convective-heat transport problems with large Peclet numbers, etc.

The numerical analysis of singularly perturbed cases has always been far from trivial because of the boundary layer behavior of the solution. These problems depend on a perturbation parameter $\epsilon$ in such a way that the solutions behave non-uniformly as $\epsilon$ tends towards some limiting value of interest. Therefore, it is important to develop some suitable numerical methods whose accuracy does not depend on $\epsilon$, i.e., which are convergent $\epsilon$-uniformly. There are a wide variety of techniques to solve these types of problems (see the books of Doolan et al. (1980) and Roos et al. (1996) for further details). Parameter-uniform numerical methods for a scalar reaction–diffusion equation have been examined extensively in the literature (see the works of Roos et al. (1996), Farrell et al. (2000), Miller et al. (1996) and the references therein), whereas for a system of singularly perturbed reaction–diffusion equations only few results (Madden and Stynes, 2003; Matthews et al., 2000; 2002; Natesan and Briti, 2007; Valanarasu and Ramanujam, 2004) have been reported.

In this paper, we treat the following system of two singularly perturbed reaction–diffusion equations:

$$L_1 \vec{u} \equiv -\epsilon u_1''(x) + a_{11}(x)u_1(x) + a_{12}(x)u_2(x) = f_1(x),$$

$$L_2 \vec{u} \equiv -\mu u_2''(x) + a_{21}(x)u_1(x) + a_{22}(x)u_2(x) = f_2(x),$$

where $\vec{u} = (u_1, u_2)^T$, $x \in \Omega = (0, 1)$, with the boundary conditions

$$\vec{u}(0) = \left(\begin{array}{c} p \\ r \end{array}\right), \quad \vec{u}(1) = \left(\begin{array}{c} q \\ s \end{array}\right).$$

Without loss of generality, we shall assume that $0 < \epsilon \leq \mu \leq 1$. The functions $a_{11}(x)$, $a_{12}(x)$, $a_{21}(x)$, $a_{22}(x)$, $f_1(x)$, $f_2(x)$ are sufficiently smooth and satisfy the following set of inequalities:
have constructed full asymptotic expansions together to show almost second-order convergence (Matthews et al., 2000) consider case (i), showing that a standard finite difference scheme is uniformly convergent on a fitted piecewise uniform mesh. They establish first-order convergence for the general case (iii). For problems with diffusion coefficients a system of two singularly perturbed reaction–diffusion equations, which is of second order convergent.

Shishkin (1995) classifies three separate cases for a system of two singularly perturbed reaction–diffusion problems with diffusion coefficients \( \epsilon, \mu \): (i) \( 0 < \epsilon = \mu \ll 1 \), (ii) \( 0 < \epsilon \ll \mu = 1 \) and (iii) \( \epsilon, \mu \) arbitrary. Matthews et al. (2000) consider case (i), showing that a standard finite difference scheme is uniformly convergent on a fitted piecewise uniform mesh. They establish first-order convergence up to a logarithmic factor in the discrete maximum norm. The same authors have also obtained a similar result for case (ii), which they have strengthened to show almost second-order convergence (Matthews et al., 2002). Madden and Stynes (2003) obtained almost first-order convergence for the general case (iii). For case (ii), Natesan and Briti (2007) developed a numerical method which is a combination of a cubic spline and a finite difference scheme.

Das and Natesan (2013) obtained almost second-order convergence for the general case (iii) in which they used central difference approximation for an outer region with cubic spline approximation for an inner region of boundary layers. Melenk et al. (2013) have constructed full asymptotic expansions together with error bounds that cover the complete range of \( 0 < \epsilon \ll \mu \ll 1 \). Rao et al. (2011) proposed a hybrid difference scheme on a piecewise-uniform Shishkin mesh and showed that the scheme generates better approximations to the exact solution than the classical central difference one. Valanarasu and Ramanujam (2004) proposed an Asymptotic Initial Value Method (AIVM) to solve (1–3), whose theoretical order of convergence is 1. Bawa et al. (2011) used a hybrid scheme for a singularly perturbed delay differential equation, which is of second order convergent.

We construct a Modified Initial Value Technique (MIVT) for 1–3 which is based on the underlying idea of the AIVM (Valanarasu and Ramanujam, 2004). The aim of the present study is to improve the order of convergence to almost second order (up to a logarithmic factor) for case (i), i.e., for \( 0 < \epsilon = \mu \ll 1 \).

First, in this technique, an asymptotic expansion approximation for the solution of the Boundary Value Problem (BVP) 1–3 has been constructed. Then, Initial Value Problems (IVPs) and Terminal Value Problems (TVPs) are formulated whose solutions are the terms of this asymptotic expansion. The IVPs and TVPs are happened to be SPPs, and therefore they are solved by a hybrid scheme similar to that by Bawa et al. (2011). The scheme is a combination of the trapezoidal scheme and a backward difference operator but also retains the second order of convergence of the trapezoidal method.

The paper is organized as follows. Section 2 presents an asymptotic expansion approximation of 1–3. The initial value problem is discussed in Section 3. Section 4 deals with the error estimates of the proposed hybrid scheme. The Shishkin mesh and the MIVT are given in Section 5. Finally, numerical examples are presented in Section 6 to illustrate the applicability of the method. The paper ends with some conclusions.

Note. Throughout this paper, we let \( C \) denote a generic positive constant that may take different values in the different formulas, but is always independent of \( N \) and \( \epsilon \). Here \( \| \cdot \| \) denotes the maximum norm over \( \Omega \).

2. Preliminaries

2.1. Maximum principle and the stability result.

**Lemma 1.** (Matthews et al., 2002) Consider the BVP system 1–3. If \( L_{11} \bar{y} \geq 0, L_{22} \bar{y} \geq 0 \) in \( \Omega \) and \( \bar{y}(0) \geq 0 \), \( \bar{y}(1) \geq 0 \), then \( \bar{y}(x) \geq 0 \) in \( \Omega \).

**Lemma 2.** (Matthews et al., 2002) If \( \bar{y}(x) \) is the solution of BVP 1–3, then

\[
\| \bar{y}(x) \| \leq \frac{1}{\gamma} \| f \| + \| \bar{y}(0) \| + \| \bar{y}(1) \|,
\]

where \( \gamma = \min \{a_{11}(x) + a_{12}(x), a_{21}(x) + a_{22}(x)\} \).

2.2. Asymptotic expansion approximation. It is well known that, by using the fundamental idea of WKB (Valanarasu and Ramanujam, 2004; Nayfeh, 1981), an asymptotic expansion approximation for the solution of the BVP 1–3 can be constructed as

\[
\bar{u}_{as}(x) = \bar{u}_R(x) + \bar{v}(x) + O(\sqrt{\epsilon}),
\]

where

\[
\bar{u}_R(x) = \begin{pmatrix} u_{R1}(x) \\ u_{R2}(x) \end{pmatrix}
\]

is the solution of the reduced problem of 1–3 and is given by

\[
a_{11}(x)u_{R1}(x) + a_{12}(x)u_{R2}(x) = f_1(x),
\]

\[
a_{21}(x)u_{R1}(x) + a_{22}(x)u_{R2}(x) = f_2(x),
\]

\( x \in [0, 1] \), and

\[
\bar{v}(x) = \begin{pmatrix} v_1(x) \\ v_2(x) \end{pmatrix}
\]

is given by

\[
v_1(x) = [p - u_{R1}(0)] \frac{a_{11}(0) + a_{12}(0)}{a_{11}(x) + a_{12}(x)} v_{L1}(x)
\]

\[
+ [q - u_{R1}(1)] \frac{a_{11}(1) + a_{12}(1)}{a_{11}(x) + a_{12}(x)} w_{R1}(x),
\]

\[
v_2(x) = [p - u_{R1}(0)] \frac{a_{11}(0) + a_{12}(0)}{a_{11}(x) + a_{12}(x)} v_{L2}(x)
\]

\[
+ [q - u_{R1}(1)] \frac{a_{11}(1) + a_{12}(1)}{a_{11}(x) + a_{12}(x)} w_{R2}(x),
\]

\[
v_{L1}(x) = \frac{a_{11}(0) + a_{12}(0)}{a_{11}(x) + a_{12}(x)} v_{L1}(x)
\]

\[
+ [q - u_{R1}(1)] \frac{a_{11}(1) + a_{12}(1)}{a_{11}(x) + a_{12}(x)} w_{R1}(x),
\]

\[
v_{L2}(x) = \frac{a_{11}(0) + a_{12}(0)}{a_{11}(x) + a_{12}(x)} v_{L2}(x)
\]

\[
+ [q - u_{R1}(1)] \frac{a_{11}(1) + a_{12}(1)}{a_{11}(x) + a_{12}(x)} w_{R2}(x),
\]
\[ v_2(x) = \left[ r - u_{R2}(0) \right] \left[ \frac{a_{21}(0) + a_{22}(0)}{a_{21}(x) + a_{22}(x)} \right] v_{L2}(x) + [s - u_{R2}(1)] \left[ \frac{a_{21}(1) + a_{22}(1)}{a_{21}(x) + a_{22}(x)} \right] w_{R2}(x). \]

Here
\[ \tilde{v}_L(x) = \left( v_{L1}(x) \right), \]
is a “left boundary layer correction” and
\[ \tilde{w}_{R}(x) = \left( w_{R1}(x) \right) \]
is a “right boundary layer correction” defined as
\[ v_{L1}(x) = \exp \left\{ - \int_0^x \sqrt{\frac{a_{11}(s) + a_{12}(s)}{\epsilon}} \, ds \right\}, \quad (6) \]
\[ v_{L2}(x) = \exp \left\{ - \int_0^x \sqrt{\frac{a_{21}(s) + a_{22}(s)}{\epsilon}} \, ds \right\}, \quad (7) \]
\[ w_{R1}(x) = \exp \left\{ - \int_x^1 \sqrt{\frac{a_{11}(s) + a_{12}(s)}{\epsilon}} \, ds \right\}, \quad (8) \]
\[ w_{R2}(x) = \exp \left\{ - \int_x^1 \sqrt{\frac{a_{21}(s) + a_{22}(s)}{\epsilon}} \, ds \right\}. \quad (9) \]

It is easy to verify that \( v_{L1}(x), v_{L2}(x), w_{R1}(x) \)
and \( w_{R2}(x) \) satisfy the following IVPs and TVPs, respectively:
\[ \sqrt{\epsilon} v'_{L1}(x) + \sqrt{\left| a_{11}(x) + a_{12}(x) \right|} v_{L1}(x) = 0, \quad (10) \]
\[ v_{L1}(0) = 1, \quad (11) \]
\[ \sqrt{\epsilon} v'_{L2}(x) + \sqrt{\left| a_{21}(x) + a_{22}(x) \right|} v_{L2}(x) = 0, \quad (12) \]
\[ v_{L2}(0) = 1, \quad (13) \]
\[ \sqrt{\epsilon} w'_{R1}(x) - \sqrt{\left| a_{11}(x) + a_{12}(x) \right|} w_{R1}(x) = 0, \quad (14) \]
\[ w_{R1}(1) = 1, \quad (15) \]
and
\[ \sqrt{\epsilon} w'_{R2}(x) - \sqrt{\left| a_{21}(x) + a_{22}(x) \right|} w_{R2}(x) = 0, \quad (16) \]
\[ w_{R2}(1) = 1. \quad (17) \]

**Theorem 1.** (Valanarasu and Ramanujam, 2004) *The zeroth order asymptotic expansion approximation \( \tilde{u}_{as} \) satisfies the inequality*
\[ \| (\tilde{u} - \tilde{u}_{as}) (x) \| \leq C \sqrt{\epsilon}, \]
where \( \tilde{u}(x) \) is the solution of the BVP (1)–(3).

**3. Initial value problem**

In this section, we describe a hybrid scheme for the following singularly perturbed initial value problem of the first order:
\[ L_{i}y(x) \equiv \epsilon f'(x) + b(x)y(x) = g(x), \quad (18) \]
\[ y(0) = A, \quad (19) \]
where \( A \) is a constant, \( x \in \Omega = (0, 1) \) and \( 0 < \epsilon \ll 1 \) is a small parameter, \( b \) and \( g \) are sufficiently smooth functions, such that \( b(x) \geq \beta > 0 \) on \( \Omega = [0, 1] \). Under these assumptions, \( (18)-(19) \) possesses a unique solution \( y(x) \) (Doolan et al., 1980).

On \( \Omega \), a piecewise uniform mesh of \( N \) mesh intervals is constructed as follows. The domain \( \Omega \) is sub-divided into two sub-intervals \([0, \sigma] \cup [\sigma, 1]\) for some \( \sigma \) that satisfy \( 0 < \sigma \leq 1/2 \). On each sub-interval, a uniform mesh with \( N/2 \) mesh intervals is placed. The interior points of the mesh are denoted by
\[ x_0 = 0, \quad x_i = \sum_{k=0}^{i-1} h_k, \quad h_k = x_{k+1} - x_k, \]
\[ x_N = 1, \quad i = 1, 2, \ldots, N - 1. \]

Clearly, \( x_N = 0.5 \) and \( \Omega^N = \{ x_i \}_{i=0}^{N} \). It is fitted to \( (18)-(19) \) by choosing \( \sigma \) to be the following functions of \( N \) and \( \epsilon \):
\[ \sigma = \min \left\{ \frac{1}{2}, \sigma_0 \epsilon \ln N \right\}, \]
where \( \sigma_0 \geq 2/\beta \). Note that this is a uniform mesh when \( \sigma = 1/2 \). Further, we denote the mesh size in the regions \([0, \sigma]\) by \( h = 2\sigma/N \) and in \([\sigma, 1] \) by \( H = 2(1 - \sigma)/N \).

We define the following hybrid scheme for the approximation of \( (18)-(19) \):
\[ L_{i}^N Y_i \equiv \begin{cases} 
\epsilon D^{-Y_i} + \frac{b_{i-1} Y_{i-1} + b_i Y_i}{2}, & 0 < i \leq \frac{N}{2}, \\
\epsilon D^{-Y_i} + b_i Y_i = g_i, & \frac{N}{2} < i \leq N, 
\end{cases} \quad (20) \]
\[ Y_0 = A, \quad (21) \]
where
\[ D^Y_i = \frac{Y_i - Y_{i-1}}{x_i - x_{i-1}} \]
and \( b_i = b(x_i), g_i = g(x_i) \).

**4. Error estimate**

**Theorem 2.** Let \( y(x) \) and \( Y_i \) be respectively the solutions of \( (18)-(19) \) and \( (20)-(21) \). Then the local truncation er-
We discuss the following two cases. First, if \( H < \epsilon \), from (27), we obtain
\[
|L^N_i (Y_i - y(x_i))| \leq C \epsilon H |y''(\xi)|,
\]
\[
\leq C |H \epsilon + H \epsilon^{-1} \exp(-\beta x_i/\epsilon)|
\]
\[
\leq C [N^{-1} \epsilon + N^{-\beta \sigma_0}].
\]  (29)

Secondly, if \( H \geq \epsilon \), then using the bounds of the derivatives of \( y(x) \) from (23), one can obtain the following:
\[
|L^N_i (Y_i - y(x_i))| \leq C \left( H \epsilon + \int_{x_i-1}^{x_i} (x_i - \xi) \epsilon^{-2} \exp(-\beta \xi/\epsilon) d\xi \right).
\]  (30)

Integrating by parts, we get
\[
\int_{x_i-1}^{x_i} (x_i - \xi) \epsilon^{-2} \exp(-\beta \xi/\epsilon) d\xi
\]
\[
\leq C \left( H \epsilon + \int_{x_i-1}^{x_i} \epsilon^{-1} \exp(-\beta \xi/\epsilon) d\xi \right)
\]
\[
\leq C \left[ H \epsilon + N^{-\beta \sigma_0} \right].
\]

Assuming that \( H < 2N^{-1} \) and \( \epsilon \leq H \), we get
\[
|L^N_i (Y_i - y(x_i))| \leq C \left( N^{-2} + N^{-\beta \sigma_0} \right).
\]  (31)

Combining all the previous results, we obtain the required truncation error. Hence, we arrive at the desired result.  

**Theorem 3.** Let \( y(x) \) be the solution of the IVP (18)–(19) and \( Y_i \) be the numerical solution obtained from the hybrid scheme (20)–(24). Then, for sufficiently large \( N \), and \( N^{-1} \sigma_0 \ln N \beta^* < 1 \), where
\[
\beta^* = \max_{0 \leq i \leq N} b(x_i),
\]
we have
\[
|y_i - y(x_i)| \leq C \left[ N^{-2} \ln N + N^{-1} \epsilon + N^{-\beta \sigma_0} \right],
\]
\[
\forall x_i \in \Pi.
\]  (32)

**Proof.** Let \( B^-_j = (2 - \rho_j b_i) \), \( B^+_j = (2 + \rho_j b_i) \) and \( b^-_j = (1 + \rho_j b_i) \), where \( \rho_i = h_i/\epsilon \).

The solution of the scheme (20)–(24) can be expressed as follows: For \( 0 \leq i \leq N/2, \)
\[
Y_i = \frac{\prod_{j=0}^{i-1} B^-_j Y_0 + \prod_{j=1}^{i} B^-_j \rho_i Y_i \prod_{j=1}^{i} B^+_j (g_0 + g_1) + \cdots + \prod_{j=1}^{i} B^+_j (g_i - 1) + g_i)}{\prod_{j=1}^{i} B^+_j}.
\]
and for $N/2 < i \leq N$, 
\begin{align*}
Y_i &= \frac{1}{\prod_{j=N/2+1}^{i} b_j} \sum_{j=N/2+1}^{i} \frac{\rho_i}{\prod_{j=N/2+2}^{i} b_j} g_{N/2+1} + \frac{\rho_i}{\prod_{j=N/2+2}^{i} b_j} g_{N/2+2} + \cdots + \frac{\rho_i}{b_i} g_i,
\end{align*}
Clearly, $B_i^+\'s$ and $b_i^+\'s$ are non-negative.
For $B_i^- > 0$, $0 < i \leq N/2$, we have
$$B_i^- = 2 - \rho_i b_i = 2 - \frac{h_i b_i}{\epsilon}.$$ 
Since $h_i = \frac{2N^{-1} \rho_0 \epsilon}{\ln N}$ and $b_i \leq \beta^*$, we have $B_i^- > 0$. Consequently, the solution satisfies the discrete maximum principle and hence there are no oscillations.

Let us define the discrete barrier function:
$$\phi_i = C \left[ N^{-2} \ln^2 N + N^{-1} \epsilon + N^{-\beta} \sigma_0 \right].$$ 
Now, choosing $C$ sufficiently large and using the discrete maximum principle, it is easier to see that
$$L_i^N(\phi_i \pm (Y_i - y(x_i))) \geq 0$$
or, equivalently,
$$L_i^N(\phi_i) \geq |Y_i - y(x_i)|.$$ 
Therefore, it follows that
$$|Y_i - y(x_i)| \leq |\phi_i|, \quad \forall x_i \in \overline{\Omega}.$$ 
Thus, we have the required $\epsilon$-uniform error bound. 

Remark 1. In Theorem 2, one can notice that the truncation error is of order $N^{-\beta} \sigma_0$ for $H > \epsilon$. It is assumed that $\beta \sigma_0 \geq 2$ and we are interested in the case of $\epsilon \leq N^{-1}$. Also, we obtain the error bound of order $N^{-1} \epsilon$ only in the interval $[\sigma, 1]$ for the case $H < \epsilon$, which is not the practical case. With these points, we conclude that the order of convergence is almost 2 (up to a logarithmic factor).

5. Mesh and the scheme

A fitted mesh method for the problem (1)–(3) is now introduced. On $\overline{\Omega}$, a piecewise uniform mesh of $N$ mesh intervals is constructed as follows. The domain $\overline{\Omega}$ is subdivided into the three subintervals as
$$\overline{\Omega} = [0, \sigma] \cup (\sigma, 1 - \sigma] \cup (1 - \sigma, 1]$$
for some $\sigma$ that satisfies $0 < \sigma \leq 1/4$. On $[0, \sigma]$ and $[1 - \sigma, 1]$, a uniform mesh with $N/4$ mesh-intervals is placed, while $[\sigma, 1 - \sigma]$ has a uniform mesh with $N/2$ mesh intervals. It is obvious that mesh is uniform when $\sigma = 1/4$. It is fitted to the problem by choosing $\sigma$ to be the function of $N$ and $\epsilon$ and
$$\sigma = \min \left\{ \frac{1}{4}, \sigma_0 \sqrt{\ln N} \right\},$$
where $\sigma_0 \geq 2/\sqrt{\beta}$. Then, the hybrid scheme (20)–(21) becomes
\begin{align}
L_i^N V_{L,1,i} &= \frac{\epsilon D^- V_{L,1,i} + \frac{1}{2} (\sqrt{a_{11,i-1} + a_{12,i-1}} V_{L,1,i-1} + \sqrt{a_{11,i} + a_{12,i}} V_{L,1,i})}{\sqrt{a_{11,i} + a_{12,i}}} = 0 \\
&\quad \text{for } 0 < i \leq N/4 \text{ and } 3N/4 < i \leq N, \\
&\quad \epsilon D^- V_{L,1,i} + \sqrt{a_{11,i} + a_{12,i}} V_{L,1,i} = 0 \\
&\quad \text{for } N/4 < i \leq 3N/4,
\end{align}

(33)

\begin{align}
V_{L,1,0} &= 1. 
\end{align}

Similarly, we can define the hybrid scheme for (12)–(13), (14)–(15) and (16)–(17).

5.1. Description of the method. In this subsection, we describe the MIVT to solve (1)–(3):

Step 1. Solve the IVP (10)–(11) by using the hybrid scheme described on the Shishkin mesh. Let $V_{L,1,i}$ be its solution.

Step 2. Solve the IVP (12)–(13) by using the hybrid scheme. Let $V_{L,2,i}$ be its solution.

Step 3. Solve the TVP (14)–(15) by using the hybrid scheme. Let $W_{R,1,i}$ be its solution.

Step 4. Solve the TVP (16)–(17) by using the hybrid scheme. Let $W_{R,2,i}$ be its solution.

Step 5. Define mesh function $U_i$ as
\begin{align}
U_i &= \left( \begin{array}{c}
U_{L,1,i} \\
U_{L,2,i} \\
U_{R,1,i} \\
U_{R,2,i}
\end{array} \right) \\
&= \left( \begin{array}{c}
\frac{p - u_{R,1}(0)}{a_{11}(0) + a_{12}(0)} \\
\frac{a_{11}(x_i) + a_{12}(x_i)}{a_{21}(0) + a_{22}(0)} \\
\frac{a_{21}(x_i) + a_{22}(x_i)}{a_{21}(0) + a_{22}(0)} \\
\frac{a_{21}(x_i) + a_{22}(x_i)}{a_{21}(0) + a_{22}(0)}
\end{array} \right) \hat{V}_{L,1,i} \\
&\quad + \left( \begin{array}{c}
\frac{r - u_{R,2}(0)}{a_{11}(x_i) + a_{12}(x_i)} \\
\frac{a_{11}(x_i) + a_{12}(x_i)}{a_{21}(x_i) + a_{22}(x_i)} \\
\frac{a_{21}(x_i) + a_{22}(x_i)}{a_{21}(x_i) + a_{22}(x_i)} \\
\frac{a_{21}(x_i) + a_{22}(x_i)}{a_{21}(x_i) + a_{22}(x_i)}
\end{array} \right) \hat{V}_{L,2,i} \\
&\quad + \left( \begin{array}{c}
\frac{g - u_{R,1}(1)}{a_{11}(1) + a_{12}(1)} \\
\frac{a_{11}(x_i) + a_{12}(x_i)}{a_{21}(1) + a_{22}(1)} \\
\frac{a_{21}(x_i) + a_{22}(x_i)}{a_{21}(1) + a_{22}(1)} \\
\frac{a_{21}(x_i) + a_{22}(x_i)}{a_{21}(1) + a_{22}(1)}
\end{array} \right) \hat{W}_{R,1,i} \\
&\quad + \left( \begin{array}{c}
\frac{s - u_{R,2}(1)}{a_{11}(x_i) + a_{12}(x_i)} \\
\frac{a_{11}(x_i) + a_{12}(x_i)}{a_{21}(x_i) + a_{22}(x_i)} \\
\frac{a_{21}(x_i) + a_{22}(x_i)}{a_{21}(x_i) + a_{22}(x_i)} \\
\frac{a_{21}(x_i) + a_{22}(x_i)}{a_{21}(x_i) + a_{22}(x_i)}
\end{array} \right) \hat{W}_{R,2,i},
\end{align}

(35)
Theorem 4. Let \( \bar{u}(x) \) be the solution of the BVP (7–9) and \( \bar{U}_i \) be the numerical solution obtained by the MIVT. Then we have

\[
\| \bar{U}_i - \bar{u}(x_i) \| \leq C \left[ N^{-2} \ln^2 N + N^{-1} \epsilon + N^{-\sqrt{\sigma_0}} + \sqrt{\epsilon} \right].
\]

Proof. Theorem 3 when applied to the IVPs (10–11), (12–13) and the TVPs (14–15), (16–17), yields

\[
|V_{L_1,i} - u_{L_1}(x_i)| \leq C \left[ N^{-2} \ln^2 N + N^{-1} \epsilon + N^{-\sqrt{\sigma_0}} \right]
\]

for \( 0 \leq x_i \leq 1 \),

\[
|V_{L_2,i} - u_{L_2}(x_i)| \leq C \left[ N^{-2} \ln^2 N + N^{-1} \epsilon + N^{-\sqrt{\sigma_0}} \right]
\]

for \( 0 \leq x_i \leq 1 \),

\[
|W_{R_1,i} - w_{R_1}(x_i)| \leq C \left[ N^{-2} \ln^2 N + N^{-1} \epsilon + N^{-\sqrt{\sigma_0}} \right]
\]

for \( 0 \leq x_i \leq 1 \),

\[
|W_{R_2,i} - w_{R_2}(x_i)| \leq C \left[ N^{-2} \ln^2 N + N^{-1} \epsilon + N^{-\sqrt{\sigma_0}} \right]
\]

for \( 0 \leq x_i \leq 1 \).

From the definitions of \( \bar{u}_{as}(x) \), \( \bar{U}_i \) and the above inequalities, we have

\[
\| \bar{u}_{as}(x_i) - \bar{U}_i \| \leq C \left[ N^{-2} \ln^2 N + N^{-1} \epsilon + N^{-\sqrt{\sigma_0}} \right],
\]

(36)

for \( x_i \in \Omega^N \). From Theorem 3, we have

\[
\| \bar{u}(x_i) - \bar{u}_{as}(x_i) \| \leq C \sqrt{\epsilon}, \quad x \in \bar{\Omega}.
\]

(37)

The desired estimate follows from the inequalities (36) and (37).

6. Numerical experiments and discussions

To show the applicability and efficiency of the present technique, two examples are provided. The computational results are given in the form of tables. The results are presented with the maximum point-wise errors for various values of \( \epsilon \) and \( N \). We have also computed the computational order of convergence, which is shown in the same table along with the maximum errors.

Example 1. Consider the following problem:

\[-\epsilon u_1''(x) + 3u_1(x) - u_2(x) = 2, \]

\[-\epsilon u_2''(x) - u_1(x) + 3u_2(x) = 3, \quad x \in (0, 1), \]

\[\bar{u}(0) = \left( \begin{array}{c} 0 \\ 0 \end{array} \right), \quad \bar{u}(1) = \left( \begin{array}{c} 0 \\ 0 \end{array} \right).\]

The exact solution of this example is not available. Therefore, to obtain the maximum pointwise errors and rates of convergence, we use the double mesh principle. By following the idea of Sun and Stynes (1995), we modify the Shishkin mesh. We calculate the numerical solution \( U^N \) on \( \Omega^N \) and the numerical solution \( \bar{U}^N \) on the mesh \( \bar{\Omega}^N \), where the transition parameter \( \sigma \) is altered slightly to \( \tilde{\sigma} = \min \{ 1/4, \sigma_0 \epsilon \ln(N/2) \} \). Note that this slightly altered value of \( \sigma \) will ensure that the positions of transition points remain the same in meshes \( \bar{\Omega}^N \) and \( \Omega^N \). Hence, the use of interpolation for the double mesh principle can be avoided. The double mesh difference is defined as

\[E^*_\epsilon = \max_{x_i, \bar{\Omega}^N} \{|U_i^N - \bar{U}_i^N|\}, \quad (38)\]

where \( U_i^N \) and \( \bar{U}_i^N \) respectively denote the numerical solutions obtained by using \( N \) and \( 2N \) mesh intervals. The rates of convergence are calculated as

\[p^*_\epsilon = \ln \frac{E^*_\epsilon}{E_{2N}^*}. \quad (39)\]

Tables 1 and 2 display respectively the maximum pointwise errors for \( u_1 \) and \( u_2 \) for several values of \( \epsilon \) and \( N \) taking \( \sigma_0 = 2 \).

Example 2. Consider the following problem:

\[-\epsilon u_1''(x) + 2(x + 1)^2 u_1(x) - (x^3 + 1) u_2(x) = 2e^x, \]

\[-\epsilon u_2''(x) - 2\cos(\pi x/4) u_1(x) + 2.2e^{-x+1} u_2(x) = 10x + 1, \]

\[x \in (0, 1), \quad \bar{u}(0) = \left( \begin{array}{c} 0 \\ 0 \end{array} \right), \quad \bar{u}(1) = \left( \begin{array}{c} 0 \\ 0 \end{array} \right).\]

Maximum pointwise errors and rate of convergence for \( u_1 \) and \( u_2 \) are given in Tables 3 and 4, respectively. From the rates of convergence one can conclude that the present method has second-order convergence up to a logarithmic factor.

7. Conclusions

In this article, a robust computational technique is proposed for solving the system of two singularly perturbed reaction–diffusion problems. It is observed that, although the backward difference operator satisfies the discrete maximum principle in the whole domain \([0, 1]\), the its order is 1 (up to a logarithmic factor). We can get the order 2 (up to a logarithmic factor) by applying the trapezoidal scheme in \([0, 1]\), but it results in small oscillations, hence the solution is not stable unless the mesh size is very small even in the outer region \([\sigma, 1]\), where a coarse mesh is enough to give satisfactory results.

In order to retain the second-order convergence of the implicit trapezoidal scheme together with the

A robust computational technique for a system of singularly perturbed reaction–diffusion equations

Vinod Kumar received his Ph.D. (mathematics) from Thapar University, Patiala, India, in 2013. He worked at SLIET, Longowal (Deemed University) and Chitkara University. His present area of interest includes parallel and scientific computations.

Rajesh K. Bawa obtained his Ph.D. in numerical computing from IIT Kanpur in 1994. Presently, he is a professor and the head of the Department of Computer Science, Punjabi University, Patiala. Before, he also served at SLIET, Longowal (Deemed University) and Thapar University at Patiala. His present area of interest is parallel and scientific computation. He has published numerous research papers in learned journals of reputed publishers such as Elsevier, Springer, Taylor and Francis, etc.

Arvind K. Lal received his M.Sc. (mathematics) in 1987 from the University of Bihar, Muzaffarpur, India, and a Ph.D. (mathematics) from the University of Roorkee, Roorkee, India (presently IIT, Roorkee) in 1995. He has been working in Thapar University, Patiala, India, since 1996. Currently, he is an associate professor at that university. His research interests include numerical analysis, theoretical astrophysics and reliability analysis.
