The interaction of linear boundary value 
and nonlinear functional conditions

by Michal Fečkan (Bratislava)

Abstract. The existence of solutions is studied for certain nonlinear differential equations with both linear and nonlinear conditions.

1. Introduction. The purpose of this paper is to study the existence of solutions of problems similar to

\[ x''' = f(x, t), \]
\[ \|x''\|_{C^0} = g(x), \]
\[ x(0) = x(1) = 0, \]

where \( f : \mathbb{R} \times [0, 1] \to \mathbb{R} \) and \( g : C^0([0, 1], \mathbb{R}) \to \mathbb{R} \) are continuous. We see that (1.1) contains two types of conditions. The first is nonlinear and functional, while the second is linear and involves boundary values. Moreover, the second condition usually leads to problems at resonances.

Problems with the first type of conditions were studied in [2]. S. A. Brykalov solved the problem

\[ x'' = f(x, t), \]
\[ \|x''\|_{C^0} = g_1(x), \]
\[ \|x\|_{C^0} = g_2(x), \]

where \( f : \mathbb{R} \times [0, 1] \to \mathbb{R} \) and \( g_1, g_2 : C^0([0, 1], \mathbb{R}) \to \mathbb{R} \) are continuous. Under additional assumptions on \( f, g_1, g_2 \), he showed the existence of at least four solutions of the problem. Hence the paper [2] suggests a method for finding multiple solutions for nonlinear ordinary differential equations with certain nonlinear, functional conditions.

On the other hand, the theory of existence of solutions for nonlinear 1991 Mathematics Subject Classification: 46N20, 47H17, 34B15.

Key words and phrases: differential equations, linear and nonlinear conditions, Fredholm operators.
boundary value problems at resonances is well-known [1]. The so-called
Landesman–Lazer conditions play an important role in that theory.

In this paper, we try to combine these two approaches to (1.1). We shall
study certain types of nonlinear ordinary differential equations with both
linear boundary conditions and nonlinear functional conditions. We were
motivated mainly by [2]; as far as the author knows, the literature on such
problems is rather limited, and their study remains a promising subject.
On the other hand, S. A. Brykalov did not consider linear boundary value
conditions which may lead to problems at resonances. Moreover, in some
sense his nonlinear functional conditions are more specific than ours. Our
setting of the problem is more general, and it embodies a broader variety
of nonlinear differential equations, due to the combination of two types of
conditions.

The plan of this paper is as follows. In the next section, we study an
abstract equation in Banach spaces, generalizing (1.1). Then we apply our
results on that equation to ordinary differential equations similar to (1.1).
Section 4 includes some remarks.

2. Abstract results. In this section, we formulate an abstract version
of (1.1) in the framework of nonlinear operators in Banach spaces. We refer
the reader to the next section for concrete forms of those operators and
spaces. We study an abstract equation of the form

\[ Lu = H(u), \quad \bar{B}(u) = D(u), \]

where \( L : X \to Y, \) \( H : Y \to Y, \) \( \bar{B} : X \to \mathbb{R}^n \) and \( D : Y \to \mathbb{R}^n \) are con-
tinuous, \( L \) is a linear operator, \( X, Y \) are Banach spaces and \( X \) is compactly
embedded into \( Y. \) Moreover, we assume \( L = L_1 \circ L_2, \) where \( L_1 : X_1 \to Y \)
and \( L_2 : X_2 \to Y \) are continuous and linear, and \( L_2 \) is Fredholm of nonneg-
ative index. Furthermore, \( X_1, X_2 \) are Banach spaces such that \( X \subset X_2 \) and
\( X_1, X_2 \) are both compactly embedded into \( Y. \) Finally, \( X \xrightarrow{L_2} X_1 \xrightarrow{L_1} Y \) and
\( \bar{B} = B \circ L_2, \) where \( B : Y \to \mathbb{R}^n \) is continuous.

The decompositions \( L = L_1 \circ L_2 \) and \( \bar{B} = B \circ L_2 \) express the interaction
of two conditions, and allow (2.1) to be rewritten in the following form:

\[
\begin{align*}
(2.2a) & \quad \begin{cases} L_1 v = H(u), & v \in X_1, \\ B(v) = D(u), & u \in Y, \end{cases} \\
(2.2b) & \quad L_2 u = v, \quad u \in X_2, \ v \in Y. 
\end{align*}
\]

Finally, we suppose \( H, D \) to be bounded, i.e., \( |H(\cdot)|_Y \leq K_1 \) and \( K_2 \leq
\end{align*}
\]

D(\cdot) \leq K_3 \) for some constants \( K_1, K_2, K_3. \) (The norm of \( Y \) will be denoted
by \( |\cdot|_Y, \) and similarly for other spaces.)

First, we study (2.2a). For this purpose, we assume the existence of a
closed subset \( \mathcal{A} \subset X_1 \) with the properties
(a) \( \forall b \in Y, |b|_Y \leq K_1, \forall d \in [K_2, K_3]\) there exists a unique \( v \in A \) such that \( L_1 v = b \) and \( B(v) = d \).

(b) The above-defined map \( (b, d) \mapsto v(b, d) \) is continuous as a map
\[
B_{K_1} \times [K_2, K_3] \to Y, \quad \text{where } B_{K_1} = \{ z \in Y \mid |z|_Y \leq K_1 \}.
\]

Remark 2.1. Assume that the map \( v \) from (a) is bounded, i.e., \( |v(\cdot, \cdot)|_{X_1} \leq M \) for a constant \( M \), and \( \dim \ker L_1 < \infty \), \( \text{Im} L_1 = Y \). Then (a) implies (b). Indeed, let \( \tilde{L}_1 \) be a right inverse of \( L_1 \). We take \( |b_i|_Y \leq K_1 \), \( b_i \to b \) in \( Y \), \( d_i \to d \), \( d_i \in [K_2, K_3] \). Then \( \{ \tilde{L}_1 b_i - v(b_i, d_i) \}_{i=1}^{\infty} \subset \ker L_1 \) is a bounded subset. Hence we can assume \( v(b_i, d_i) \to w \) in \( X_1 \). This implies \( L_1 w = b \) and \( B(w) = d \). Thus \( w = v(b, d) \) and the assertion is proved.

Now we insert the map \( V(u) = v(H(u), D(u)) \) into (2.2b):

\[
(2.3) \quad L_2 u = V(u), \quad u \in X_2.
\]
Since \( L_2 \) is Fredholm, (2.3) can be handled in the standard way [1]. So, (2.3) is equivalent to

\[
(2.4) \quad \begin{align*}
  u_1 &= \tilde{L}_2 QV(u_1 + u_2), \\
  u_2 &= u_2 + PV(u_1 + u_2), \\
  u_2 &\in \ker L_2, \quad u_1 \in \tilde{X}_2, \quad \ker L_2 \oplus \tilde{X}_2 = X_2, \\
  Q : Y &\to \text{Im} L_2, \quad Q + P = I, \\
  Q &\text{ is a continuous projection}, \\
  \tilde{L}_2 &= \left( L_2 / \tilde{X}_2 \right)^{-1}.
\end{align*}
\]

Summing up, we obtain

**Proposition 2.2.** Under the above conditions (a), (b), the equation (2.1) can be rewritten in the form (2.4).

Remark 2.3. The set \( A \) has been introduced for the same purpose as in [2]. By choosing another set \( A \), we can show the existence of multiple solutions of (2.1).

Now we assume

\[
(\text{P1}) \quad \lim_{r \to \infty} H(r u_2 + u_1) = H_\infty(u_2), \\
(\text{P2}) \quad \lim_{r \to \infty} D(r u_2 + u_1) = D_\infty(u_2),
\]
uniformly in \( u_1 \) from bounded subsets and \( u_2 \in \ker L_2, |u_2|_{X_2} = 1 \).

Moreover, suppose the maps

\[
(\text{P3}) \quad H_\infty : S_1 = \{ u \in \ker L_2 \mid |u|_{X_2} = 1 \} \to Y \text{ and } D_\infty : S_1 \to \mathbb{R}^n \text{ are continuous.}
\]
Of course, (P1–3) imply the boundedness of $H, D$, respectively, and $|H_{\infty}(\cdot)|_{Y} \leq K_{1}, D_{\infty}(\cdot) \in [K_{2}, K_{3}]$. Hence we can define $V_{\infty} = v(H_{\infty}, D_{\infty})$. It is clear that
\[
\lim_{r \to \infty} V(ru_{2} + u_{1}) = V_{\infty}(u_{2})
\]
uniformly in $u_{4}$ from bounded subsets and $u_{2} \in S_{1}$. Now applying [1, (5.4.32) Theorem] we obtain

**Theorem 2.4.** Let the conditions (a), (b), and (P1–3) be satisfied. Assume that $PV_{\infty}(a) \neq 0$, $\forall a \in S_{1}$, and that the stable homotopy class of $\eta(a) = PV_{\infty}(a)/[PV_{\infty}(a)]_{Y}$, $\eta : S_{1} \simeq S^{m-1} \to S^{m^* - 1}$, is nontrivial, where $m = \dim \ker L_{2}$ and $m^* = \text{codim} \text{Im} L_{2}$. Then the equation (2.1) has a solution.

Now we shall study a special case of (2.1). We make the following assumption:

(H1) $\text{Im } L_{1} = Y$, $\ker L_{1} = \mathbb{R}v_{0}$, $B : Y \to [\tilde{d}, \infty) \subset \mathbb{R}$, $\tilde{d} \to -\infty$, is continuous and strictly convex, and $B^{-1}([a, b])$ is bounded for any $-\infty < a \leq b < \infty$.

We put
\[
A_{+} = \{ v \in X_{1} | B(v + cv_{0}) \geq B(v), \forall c > 0 \},
\]
\[
A_{-} = \{ v \in X_{1} | B(v + cv_{0}) \geq B(v), \forall c < 0 \}.
\]

We note that $\tau : c \to B(v + cv_{0})$ is a strictly convex real function such that $\tau(\mathbb{R}) \subset [\tilde{d}, \infty)$ and $\tau^{-1}([a, b])$ is bounded for any $-\infty < a \leq b < \infty$. Hence there is a unique $c_{0} \in \mathbb{R}$ such that $c_{0}$ minimizes $\tau$, and $\tau$ is increasing for $c > c_{0}$ and decreasing for $c < c_{0}$. Thus $v + c_{0}v_{0} \in A_{+} \cap A_{-}$ and $A_{-} \cup A_{+} = X_{1}$.

Now we suppose

(H2) $D : Y \to \mathbb{R}$ and $H : Y \to Y$ are continuous and $|H(\cdot)|_{Y} \leq K_{1}, K_{2} \leq D(\cdot) \leq K_{3}$ for some constants $K_{1}, K_{2}, K_{3}$.

(H3) For any $v \in A_{-} \cap A_{+}$, if $L_{1}v = b, |b|_{Y} \leq K_{1}$, then $B(v) \leq K_{2} - \delta$ for some fixed $\delta > 0$.

Let us solve $L_{1}v = b, |b|_{Y} \leq K_{1}, B(v) = d, d \in [K_{2}, K_{3}]$. Since $\text{Im } L_{1} = Y$, $\dim \ker L_{1} < \infty$, there is a right inverse $\tilde{L}_{1}$ of $L_{1}$. We solve
\[
B(\tilde{L}_{1}b + cv_{0}) = d.
\]
According to (H2–3) there are no solutions $c$ of (2.5) satisfying
\[
\tilde{L}_{1}b + cv_{0} \in A_{-} \cap A_{+}.
\]
Hence (2.5) has precisely two solutions $c_{\pm} = c_{\pm}(b, d)$ such that
\[
\tilde{L}_{1}b + c_{\pm}v_{0} \in A_{\pm}, \quad \tilde{L}_{1}b + c_{\pm}v_{0} \notin A_{+} \cap A_{-}.
Moreover, $B^{-1}([K_2, K_3])$ is a bounded subset. Hence $c_{\pm} (\cdot, \cdot)$ is bounded as well. Summing up, we have

**Proposition 2.5.** If the hypotheses (H1–3) are satisfied, then the assumptions (a), (b) hold with $A = A_{\pm}$.

**Proof.** (a) follows immediately, and (b) from Remark 2.1.

Applying Theorem 2.4 in the framework of Proposition 2.5, we can find at least two solutions for (2.1).

**Theorem 2.6.** If the hypotheses (H1–3) are satisfied and $L_2$ is an isomorphism, then (2.1) has at least two solutions.

**Proof.** In this case, (2.4) has the form $u_1 = L_2 V(u_1)$ and $V$ is bounded. Further, $V$ depends on $A = A_{\pm}$. Applying the Schauder fixed point theory finishes the proof.

Now, assume in Theorem 2.4 that index $L_2 = 0$ and dim ker $L_2 = 1$. Then $S_1 \simeq \{-1, 1\}$, $H_{\pm \infty} (\pm 1) \equiv H_{\pm \infty}$, $D_{\pm \infty} (\pm 1) \equiv D_{\pm \infty}$ and $V_{\pm \infty} (\pm 1) \equiv V_{\pm \infty}$. Moreover, $V_{\pm \infty}$ are uniquely determined by

$$(2.6) \quad L_1 V_{\pm \infty} = H_{\pm \infty}, \quad B(V_{\pm \infty}) = D_{\pm \infty}, \quad V_{\pm \infty} \in A.$$ 

The nontriviality of the stable homotopy class of $\eta$ means that $PV_{-\infty}$ and $PV_{+\infty}$ have opposite signs.

Note that the above arguments can be used for more general equations than (2.1). For instance, consider the following system of equations instead of (2.2a,b):

$$\begin{align*}
L_1 v &= H(u), \\
B(v) &= D(u), \\
L_2 u &= E(v),
\end{align*}$$

where $L_1$, $L_2$, $B$, $H$, $D$ have the properties (a), (b) and (P1–3), and $E : Y \to Y$ is continuous. Then we deal with the map $\overline{\eta} = P E \circ V_{\infty} | \cdot | P E \circ V_{\infty} | Y$ instead of $\eta$ in Theorem 2.4.

Finally, there is a special class of (2.1) which naturally satisfies (H2–3). Assume $\text{Im} L_1 = Y$, $\ker L_1 = \mathbb{R} v_0$, and $B(u) = \langle u, u \rangle$ for a symmetric, positive definite, continuous bilinear form $\langle \cdot, \cdot \rangle$ on $Y$. We see that in this case

$$\mathcal{A}_+ = \{ v \in X_1 \mid \langle v, v_0 \rangle \geq 0 \}, \quad \mathcal{A}_- = \{ v \in X_1 \mid \langle v, v_0 \rangle \leq 0 \},$$

$$\mathcal{A}_- \cap \mathcal{A}_+ = \{ v \in X_1 \mid \langle v, v_0 \rangle = 0 \}.$$

Hence $\mathcal{A}_- \cap \mathcal{A}_+ \oplus \mathbb{R} v_0$ is an orthogonal decomposition of $X_1$ with respect to $\langle \cdot, \cdot \rangle$.

Let us solve $L_1 v = b$, $|b|_Y \leq K_1$, $v \in \mathcal{A}_- \cap \mathcal{A}_+$. This equation has the unique solution $v = L_1^{-1} b$, where $L_1^{-1} : Y \to \mathcal{A}_- \cap \mathcal{A}_+$ is the inverse of $L_1$. Then
B(v) = (L_1^{-1} b, L_1^{-1} b) \equiv \tilde{B}(b).

Since X_1 is compactly embedded into Y and \langle \cdot, \cdot \rangle is continuous on Y \times Y, there is a smallest number c_L_1 such that

\begin{equation}
\tilde{B}(b) \leq c_L_1 |b|^2, \quad \forall b \in Y.
\end{equation}

**Theorem 2.7.** Assume \text{Im} L_1 = Y, \text{ker} L_1 = \mathbb{R} v_0, and \( B(u) = \langle u, u \rangle \) for a symmetric, positive definite, continuous bilinear form \( \langle \cdot, \cdot \rangle \) on Y. Let (H2) be satisfied. If

\begin{equation}
c_L_1 K_1^2 \leq K_2 - \delta
\end{equation}

for some fixed \( \delta > 0 \), then (H3) holds as well.

**Proof.** The proof follows immediately by (2.8) and (2.9).

**3. Applications.** We return to (1.1) with \( g(u) = G(||u||_{C^0}), G : \mathbb{R} \rightarrow \mathbb{R} \) continuous. We apply the results of Section 2 by putting

\( X = \{ z \in C^3([0, 1], \mathbb{R}) \mid z(0) = z(1) = 0 \}, \quad Y = C^0([0, 1], \mathbb{R}), \)

\( X_1 = C^1([0, 1], \mathbb{R}), \quad X_2 = \{ z \in C^2([0, 1], \mathbb{R}) \mid z(0) = z(1) = 0 \}, \)

\( L u = u'' \), \( H(u) = f(u, \cdot) \),

\( B(u) = ||u''||_{C^0}, \quad B(u) = ||u||_{C^0}, \)

\( L_1 v = v', \quad L_2 v = v'' \)

\( D(u) = G(||u||_{C^0}). \)

First of all, we establish hypotheses (H1–3): (H1) is clear. (H2) is satisfied provided

\begin{equation}
|f(\cdot, \cdot)| \leq K_1, \quad 0 < K_2 \leq G(\cdot) \leq K_3.
\end{equation}

In this case (see (H1)) \( v_0(\cdot) \equiv 1 \) and (see [2])

\( A_+ = \{ v \in X_1 \mid \max_{[0, 1]} v \geq -\min_{[0, 1]} v \}, \quad A_- = \{ v \in X_1 \mid \max_{[0, 1]} v \leq -\min_{[0, 1]} v \}, \)

\( A_- \cap A_+ = \{ v \in X_1 \mid \max_{[0, 1]} v = -\min_{[0, 1]} v \}. \)

Hence (see [2]) \( v \in A_- \cap A_+ \) implies

\( ||v||_{C^0} = \left( \max_{[0, 1]} v - \min_{[0, 1]} v \right) / 2 \leq \int_0^1 |v'(t)| \, dt / 2 \leq ||v'||_{C^0} / 2. \)

Thus, if \( v \in A_- \cap A_+, \ v' = b \leq K_1 \) then

\( B(v) = ||v||_{C^0} \leq ||v'||_{C^0} / 2 = \| b \|_{C^0} / 2 \leq K_1 / 2. \)

Hence (H3) is satisfied if

\begin{equation}
K_1 / 2 \leq K_2 - \delta, \quad \text{for a } \delta > 0.
\end{equation}
It is clear that $L_2$ is an isomorphism. Applying Theorem 2.6 we have

**Theorem 3.1.** Assume (3.1–2). Then (1.1) has at least two solutions.

Next we study

$$(3.4)\quad v' = f(u, t), \quad \|v\|_{C^0} = G(\|u\|_{C^0}), \quad u' = e(v), \quad u(0) = u(1),$$

where $f, G$ are continuous satisfying (3.1–2), and $e : \mathbb{R} \to \mathbb{R}$ is continuous. We already know that (3.1–2) imply (a), (b) for (2.7). Here $E(v)(t) = e(v(t)), \forall t$, in the framework of (2.7).

Now we establish the conditions (P1–3) for this case by putting

$$(3.3)\quad \begin{align*}
\lim_{r \to \pm \infty} f(r, t) &= f_\pm(t) \quad \text{uniformly in } t \in [0, 1], \\
\lim_{r \to \infty} G(r) &= G_\infty.
\end{align*}$$

Since $L_2v = \{v' \mid v(0) = v(1)\}$ in this case for (2.7), it is clear that $\dim \ker L_2 = 1$, $\ker L_2 = \{v \equiv \text{const}\}$, and $Pv = \int_0^1 v(t) dt$, where we identify constant functions with numbers.

Hence we can apply the ideas from the end of Section 2. We shall find the map $\overline{\eta}$ for this case. Here

$$(3.2)\quad H_\pm = f_\pm(\cdot), \quad D_\pm = G_\infty.$$ 

We derive $V_\pm$ from (2.6):

$$(V_+)_\infty(t) = -\int_t^1 f_+(s) ds + G_\infty, \quad (V_-)_\infty(t) = \int_0^t f_-(s) ds + G_\infty$$

for $A = A_+$, and

$$(V_+)_\infty(t) = \int_0^t f_+(s) ds - G_\infty, \quad (V_-)_\infty(t) = -\int_t^1 f_-(s) ds - G_\infty$$

for $A = A_-$. We have used (3.2) and the inequalities $|f_\pm(\cdot)| \leq K_1, G_\infty \geq K_2$.

Finally, we compute

$$PE \circ V_\pm = \int_0^t e\left(-\int_0^t f_\pm(s) ds \pm G_\infty\right) dt$$

and

$$PE \circ V_\mp = \int_0^t e\left(\int_0^t f_\pm(s) ds \mp G_\infty\right) dt.$$
Summing up, we obtain

**Theorem 3.2.** Assume (3.1–3). If
\[
\int_0^1 e\left(-\int_0^t f_+(s) \, ds + G_\infty\right) dt \cdot \int_0^1 e\left(\int_0^t f_- (s) \, ds + G_\infty\right) dt < 0,
\]
\[
\int_0^1 e\left(\int_0^t f_+(s) \, ds - G_\infty\right) dt \cdot \int_0^1 e\left(-\int_0^t f_- (s) \, ds - G_\infty\right) dt < 0,
\]
then (3.4) has at least two solutions. Moreover, if at least one of these inequalities holds, then (3.4) has a solution.

**Proof.** The proof follows immediately from the note at the end of Section 2 pertinent to (2.7) provided that we take either \(A = A_+\) or \(A = A_-\). Indeed, according to the above derivation we have
\[
\bar{\eta}(+1)/\int_0^1 e\left(-\int_0^t f_+(s) \, ds + G_\infty\right) dt > 0,
\]
\[
\bar{\eta}(-1)/\int_0^1 e\left(\int_0^t f_- (s) \, ds + G_\infty\right) dt > 0
\]
for \(A = A_+\), and
\[
\bar{\eta}(+1)/\int_0^1 e\left(\int_0^t f_+(s) \, ds - G_\infty\right) dt > 0,
\]
\[
\bar{\eta}(-1)/\int_0^1 e\left(-\int_0^t f_- (s) \, ds - G_\infty\right) dt > 0
\]
for \(A = A_-\). The assumptions of Theorem 3.2 express the nontriviality of the stable homotopy class of \(\bar{\eta}\) for \(A = A_+\) and \(A = A_-\), respectively.

To apply Theorem 2.7, let us consider
\[
u'' = f(u, t),
\]
(3.5)
\[
\int_0^1 (u''(t))^2 \, dt = G(\|u\|_{C^0}),
\]
\[u(0) = u(1) = 0,
\]
where \(f, G\) are continuous and satisfy (3.1).

**Theorem 3.3.** If
\[
K_1^2/\pi^2 \leq K_2 - \delta \quad \text{for some fixed } \delta > 0,
\]
then (3.5) has at least two solutions.
Proof. We apply Theorems 2.6 and 2.7. For this purpose, we have to verify (2.9). We have
\[ L_1 v = v', \quad \langle u, v \rangle = \int_0^1 u(t)v(t) \, dt \]
in the framework of Theorem 3.1 for this case. So we obtain
\[ L_1 v = b, \quad v \in A_0 \cap A_+ \iff v' = b, \quad \int_0^1 v(t) \, dt = 0. \]
Note that the sets \( A_-, A_+, A_0 \cap A_+ \) are defined by the formulas preceding Theorem 2.7.

Hence (see (2.8))
\[ \widetilde{B}(b) = \int_0^1 v(t)^2 \, dt = \int_0^1 w'(t)^2 \, dt = \int_0^1 b(t)w(t) \, dt, \]
where
\[ w(t) \equiv -\int_0^t v(s) \, ds, \quad w'' = -b, \quad w(0) = w(1) = 0. \]
On the other hand, by Wirtinger’s inequality we have for any \( u \in C^2 \) with \( u(0) = u(1) = 0 \),
\[ \pi^2 \|u\|_{L^2}^2 = \pi^2 \int_0^1 u(t)^2 \, dt \leq -\int_0^1 u''(t)u(t) \, dt \leq \|u''\|_{L^2} \|u\|_{L^2}, \]
and so \( \pi^2 \|u\|_{L^2} \leq \|u''\|_{L^2} \). Thus
\[ \widetilde{B}(b) = \int_0^1 b(t)w(t) \, dt \leq \|w\|_{L^2} \|b\|_{L^2} \leq \frac{1}{\pi^2} \|b\|_{C^0}^2. \]
This implies \( c_{L_1} \leq 1/\pi^2 \). The proof is finished, since (3.6) implies (2.9).

4. Concluding remarks

Remark 4.1. First of all, we show that the validity of the assumptions of Theorem 3.2 strongly depends on the choice of the function \( e \). If \( e(z) \equiv z \) then (3.4) is a second-order differential equation
\[ u'' = f(u, t), \]
(4.1)
\[ \|u'\|_{C^0} = G(\|u\|_{C^0}), \quad u(0) = u(1), \]
and (2.7) is precisely (2.2a,b). The assumptions of Theorem 3.2 are never satisfied for this case. This follows easily from \( |f_{\pm}(\cdot)| \leq K_1, G_\infty \geq K_2 \) and \( 2K_2 > K_1 \), since the integral inequalities are not satisfied.
On the other hand, it is also not hard to verify that the conditions (3.1–2) for the case \( e(z) \equiv z \) in (3.4) imply the nonexistence of solutions for (3.4). Indeed, if \( v \) is a solution of (3.4) for this case, then

\[
\|v'\|_{C^0} \leq K_1, \quad \|v\|_{C^0} \geq K_2,
\]

\[
\int_0^1 v(t) \, dt = 0, \quad v \in A_+ \cup A_-.
\]

Assume \( v \in A_+ \) (the case \( v \in A_- \) is similar). Hence

\[
\max_{[0,1]} v = v(t_{\text{max}}) = \|v\|_{C^0} \geq K_2
\]

and \( v(t) = v(t_{\text{max}}) + \int_{t_{\text{max}}}^t v'(s) \, ds \). Thus

\[
0 = \frac{1}{2} \int_0^1 v(t) \, dt \geq K_2 - \frac{1}{2} \int_0^1 K_1 \, ds \, dt = K_2 - \frac{K_1}{2} > 0 \quad \text{(by (3.2))}.
\]

This is a contradiction, proving the nonexistence of solutions for (4.1) under the conditions (3.1–2).

Remark 4.2. Of course, the results of Section 2 suggest a broader variety of equations than (1.1), (3.4) and (3.5). The derivation of assumptions (H1–3), (P1–3) is similar, but it is generally more complicated. We have chosen the above simple examples as an illustration for possible applications of our method. Moreover, the hypotheses (H1–3) can be generalized to the case \( \infty > \dim \ker L_1 > 1, \, \text{Im} L_1 = Y \). For instance, consider the following system of equations:

\[
\begin{align*}
\frac{d^3 u_1}{dt^3} &= f_1(u_1, \ldots, u_k, t), \\
& \vdots \\
\frac{d^3 u_k}{dt^3} &= f_k(u_1, \ldots, u_k, t), \\
\|u_1''\|_{C^0} &= G_1(\|u_1\|_{C^0}, \ldots, \|u_k\|_{C^0}), \\
& \vdots \\
\|u_k''\|_{C^0} &= G_k(\|u_1\|_{C^0}, \ldots, \|u_k\|_{C^0}), \\
u_1(0) &= u_1(1) = \ldots = u_k(0) = u_k(1) = 0,
\end{align*}
\]

where \( f_1, \ldots, f_k : \mathbb{R}^k \times [0,1] \to \mathbb{R} \) and \( G_1, \ldots, G_k : \mathbb{R}^k \to \mathbb{R} \) are continuous and satisfy

\[
|f_i| \leq K_{1i}, \quad 0 < K_{2i} \leq G_i \leq K_{3i}, \quad i = 1, \ldots, k,
\]

for some constants \( K_{ji}, i = 1, \ldots, k, \, j = 1, 2, 3 \), such that
for some fixed $\delta > 0$.

Then applying the procedure of Section 3 (see the arguments before Theorem 3.1), we conclude that (4.2) has at least $2^k$ solutions. Note that in this case $L_1(u_1, \ldots, u_k) = (u'_1, \ldots, u'_k)$ and $\dim \ker L_1 = k$.

Remark 4.3. If the equation (3.4) depends in some way on a parameter in Theorem 3.2, then we may find three domains of the parameter for which, respectively, this equation has no, at least one and at least two solutions. This remark holds generally. To be more concrete, we return to the problem (4.1) from Remark 4.1. We embed this problem in the following family of equations:

\begin{align}
(4.3) \\
&u'' = f(u, t), \\
&\|u' + \lambda\|_{C^0} = G(\|u\|_{C^0}), \\
&u(0) = u(1),
\end{align}

where $\lambda \in \mathbb{R}$ is a parameter. We assume the validity of (3.1–3). By putting $e(v) = v - \lambda$, we can apply the method of Section 3 used for (3.4). Conditions similar to those of Theorem 3.2 read as follows:

\begin{align}
(4.4) \\
&\left( -\int_0^1 \int_0^t f_+(s) \, ds \, dt + G_\infty - \lambda \right) \cdot \left( -\int_0^1 \int_0^t f_-(s) \, ds \, dt + G_\infty - \lambda \right) < 0, \\
&\left( \int_0^1 \int_0^t f_+(s) \, ds \, dt - G_\infty - \lambda \right) \cdot \left( -\int_0^1 \int_0^t f_-(s) \, ds \, dt - G_\infty - \lambda \right) < 0.
\end{align}

Assume $f_\pm(s) \equiv f_\pm$ for some constants $0 > f_- > -f_+$. Then (4.4) has the form

\begin{align}
(4.5) \\
&G_\infty - f_+/2 < \lambda < G_\infty + f_-/2, \\
(4.6) \\
&-G_\infty - f_-/2 < \lambda < -G_\infty + f_+/2.
\end{align}

Note that $G_\infty > |f_\pm|/2$, since (3.1–3) hold. Hence

\begin{align}
&f_+/2 - G_\infty < 0 < G_\infty - f_+/2.
\end{align}

On the other hand, using the same arguments as in Remark 4.1 we see that if (4.3) has a solution then

\begin{align}
(4.7) \\
&K_2 - K_1/2 \leq |\lambda| \leq K_3 + K_1/2.
\end{align}

Indeed, the difference between this case and the one in Remark 4.1 is only the relation

\[ \int_0^1 v(t) \, dt = \lambda, \]

since $v = u' + \lambda$ for this case.
Summarizing, we obtain:

1. If (4.7) does not hold then (4.3) has no solution.
2. If either (4.5) or (4.6) holds then (4.3) has at least one solution.

Of course, the result of Remark 4.1 is contained in the above statement.
