Abstract. The notion of an \((n, r)\)-coloring for a link diagram generalizes the idea of an \(n\)-coloring introduced by R. H. Fox. For any positive integer \(n\) the various \((n, r)\)-colorings of a diagram for an oriented link \(l\) correspond in a natural way to the periodic points of the representation shift \(\Phi_{\mathbb{Z}/n}(l)\) of the link. The number of \((n, r)\)-colorings of a diagram for a satellite knot is determined by the colorings of its pattern and companion knots together with the winding number.

1. Introduction. Tricoloring, introduced by R. H. Fox around 1960, is an elementary technique that distinguishes a trefoil knot from a trivial knot [CrFo], [Fo1], [Fo2]. A tricoloring of a link diagram is an assignment of colors to the arcs of the diagram using three colors such that at any crossing either all three colors appear or only one color appears. Any diagram has a trivial, monochromatic tricoloring — in fact, three of them. It is easily checked that the number of tricolorings of a diagram is unaffected by Reidemeister moves and hence is a numerical invariant of the link. We can deduce that a trefoil knot is different from a trivial knot simply by observing that the former has a nontrivial tricoloring. Complete details of the argument can be found in [Pr].

By broadening our palette, using \(n\) colors identified with the elements of the cyclic group \(\mathbb{Z}/n\), we arrive at the more general notion of \(n\)-coloring. An \(n\)-coloring of a link diagram is an assignment of colors to the arcs such that at any crossing the sum of the colors of the undercrossings is equal to twice the color of the overcrossing modulo \(n\). The idea but not the terminology can be found in Chapter 10 of [Fo1]. (The necessary mathematics was known to Reidemeister [Re].) Again one can check that the number of \(n\)-colorings of a diagram is unchanged by Reidemeister moves. Figure 1 shows a nontrivial 5-coloring of the figure eight knot \(4_1\). It is known that the knot has a nontrivial \(n\)-coloring if and only if \(n\) is a multiple of 5.

1991 Mathematics Subject Classification: Primary 57Q45; Secondary 54H20.

The paper is in final form and no version of it will be published elsewhere.
In this paper we introduce a further generalization of tricoloring called \((n, r)\)-coloring, where \(n\) and \(r\) are positive integers and \(r \geq 2\). Any \(n\)-coloring is an \((n, 2)\)-coloring and conversely. For any link and positive integer \(n\), the \((n, r)\)-colorings for all \(r\) can be determined from a single finite graph \(\Gamma\). The graph \(\Gamma\) describes a representation shift introduced in [SiWi1] using techniques of symbolic dynamical systems (see also [SiWi2]). We use the techniques to compute the number of \((n, r)\)-colorings of a satellite knot in terms of the colorings of its pattern and companion knots.

We are grateful to Pat Gilmer and Józef Przytycki for helpful comments.

2. \((n, r)\)-colorings and representations

Definition 2.1. Assume that \(D\) is a diagram of an oriented link. An \((n, r)\)-coloring, for positive integers \(n\) and \(r\) with \(r \geq 2\), is an assignment of \((r - 1)\)-tuples (color vectors) \(C \in (\mathbb{Z}/n)^{r-1}\) to the arcs of \(D\) such that at any crossing

\[
(C_i - C_k) \cdot S_r = C_j - C_k.
\]

Here \(C_k\) corresponds to the overcrossing, \(C_i, C_j\) correspond to the undercrossings, \(\epsilon = \pm 1\) is the algebraic sign of the crossing (see Figure 2), and \(S_r\) is the companion matrix of the cyclotomic polynomial of degree \(r - 1\); i.e.,

\[
S_r = \begin{pmatrix}
0 & 0 & \ldots & 0 & -1 \\
1 & 0 & \ldots & 0 & -1 \\
0 & 1 & \ldots & 0 & -1 \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
0 & 0 & \ldots & 1 & -1
\end{pmatrix}.
\]

When \(r = 2\) condition (2.1) reduces to the familiar \(n\)-coloring condition that the sum of the colors of the undercrossings is equal to twice the color of the overcrossing modulo \(n\).

Given any diagram \(D\) of an oriented link we will denote the number of its \((n, r)\)-colorings by \(\text{col}_{n,r}(D)\). The following result can be proved by elementary techniques. However, it will also follow from results in Section 4 (see Theorem 4.3).
Proposition 2.2. If $D$ and $D'$ are any two diagrams of an oriented link $l$, then $\text{col}_{n,r}(D) = \text{col}_{n,r}(D')$. Consequently, $\text{col}_{n,r}(D)$ is an invariant $\text{col}_{n,r}(l)$ of the link.

Proof. The diagram $D$ can be converted into $D'$ by a finite sequence of Reidemeister moves. It suffices to check that the number of $(n,r)$-colorings of any diagram is unaffected by each of the three Reidemeister moves and their inverses. We leave the details to the reader.

Assume that $D$ is a diagram for an oriented link $l$. The same diagram with reversed orientation, denoted by $r(D)$, is a diagram for a link $r(l)$. The set of $(n,r)$-colorings of $D$ is in one-to-one correspondence with the set of $(n,r)$-colorings of $r(D)$. In fact, given an $(n,r)$-coloring of $D$ we obtain an $(n,r)$-coloring of $r(D)$ by reversing the order of the components of each color vector. Consequently, the number $\text{col}_{n,r}(k)$ is an unoriented knot invariant. However, changing the orientation of only some of the components of a link $l$ can change $\text{col}_{n,r}(l)$ when $r > 2$ (see Example 4.4).

Proposition 2.3. Assume that $D$ is a diagram for an oriented link $l$. If $D$ can be $(n,r)$-colored for some $n$ and $r$, then $D$ can be $(an,br)$-colored for any positive integers $a$ and $b$.

Proof. Since $\mathbb{Z}/n$ can be embedded as a subgroup in $\mathbb{Z}/an$, it is immediate that $D$ can be $(an,r)$-colored. Assume that we have an $(an,r)$-coloring of $D$. Replacing each color vector $(c_1, \ldots, c_{r-1})$ by $(c_1, \ldots, c_r, c_1, \ldots, c_{r-1})$, where $c_r = -c_1 - \ldots - c_{r-1}$, results in an $(an,2r)$-coloring of $D$. By induction $D$ can be $(an,br)$-colored.

Definition 2.4. Assume that $D$ is a diagram for an oriented link with a distinguished arc $\delta$. A based $(n,r)$-coloring of $D$ is an $(n,r)$-coloring in which $\delta$ receives the trivial color vector.

Since the set of all $(n,r)$-colorings of $D$ obviously forms a module over $\mathbb{Z}/n$, the number of based $(n,r)$-colorings of $D$ is independent of the distinguished arc $\delta$. We will denote the number of based $(n,r)$-colorings of $D$ by $\text{col}_{n,r}^0(D)$. Clearly $\text{col}_{n,r}(D) = n^{r-1} \cdot \text{col}_{n,r}^0(D)$. It follows immediately from Proposition 2.2 that $\text{col}_{n,r}^0(D)$ is also an invariant $\text{col}_{n,r}^0(l)$ of the link.

Example 2.5. No diagram for the figure eight knot can be tricolored (i.e., $(3,2)$-colored) in a nontrivial manner. Figure 3 shows that a diagram can be nontrivially $(3,4)$-colored.

Fig. 3. Based $(3,4)$-coloring of figure eight knot diagram

3. Representation shifts associated to links. Let $l = l_1 \cup \ldots \cup l_\mu$ be any oriented link with tubular neighborhood $N = N_1 \cup \ldots \cup N_\mu$. Let $G$ denote the group $\pi_1(S^3 - l, \ast)$
of the link, where the basepoint * is chosen on the boundary ∂N₁, and let x be the class of a meridian m of l₁ (with orientation induced by l₁.) The total linking number homomorphism χ : G → Z is the homomorphism that maps each meridian of l to 1 ∈ Z. We will denote the kernel of χ by K. If μ = 1 then l is a knot, χ is the abelianization homomorphism and K is the commutator subgroup [G, G].

**Definition 3.1.** Let Σ be a finite group. The representation shift ΦΣ(l) (or simply ΦΣ) of the link l is the set Hom(K, Σ) of representations ρ : K → Σ together with the shift map σΣ : ΦΣ → ΦΣ defined by σΣρ(a) = ρ(x⁻¹ax) for all x ∈ K. The set ΦΣ has a natural topology determined by the basis sets of the shift map σ of ΦΣ. One easily checks using the uniqueness up to isotopy of tubular neighborhoods that the link type of l determines the representation shift (ΦΣ, σΣ) up to topological conjugacy. This implies, in particular, that the set Fix σΣ = {ρ : σΣρ = ρ} of period r representations is an invariant of l for each r ≥ 0.

Theorem 3.1 of [SiWi1] states that the representation shift ΦΣ is a special sort of dynamical system known as a shift of finite type. Such a system can be completely described by a finite directed graph Γ. The elements of ΦΣ correspond to the bi-infinite paths in Γ in such a way that the representations with period r correspond to the closed paths of length r. We will construct Γ for a specific example and then describe the general construction.

**Example 3.2.** We consider the knot k = 5₂ oriented as in Figure 4a with Wirtinger generators indicated. The group G = π₁(S³ − k, *) has presentation

\[ (x₁, x₂, x₃, x₄, x₅ \mid x₃x₂ = x₂x₁, x₂x₃ = x₃x₄, x₅x₁ = x₁x₂, x₄x₅ = x₅x₃). \]

We use the first three relators to eliminate x₃, x₄ and x₅ from the presentation, obtaining

\[ (x₁, x₂ \mid x₂x₁⁻¹x₂x₁⁻¹x₁x₂x₁⁻¹x₂x₁⁻¹x₂x₁⁻¹x₁x₂x₁⁻¹x₁⁻¹). \]

The Reidemeister–Schreier Theorem [LySc] enables us to find a presentation for the kernel K, which is the commutator subgroup of G. First we replace x₂ by x₁a (i.e., we introduce a new generator a and eliminate x₂ by Tietze moves). For notational convenience we will write x instead of x₁. The following presentation for G results.

\[ (x, a \mid a² \cdot xa⁻¹ \cdot x⁻¹ \cdot x² \cdot x⁻² \cdot xa⁻² \cdot x⁻¹) \]

The kernel K is generated by the elements aᵢ, i ∈ Z, where aᵢ = x⁻ⁱaxⁱ. Defining relations are obtained by conjugating the relation in the last presentation by powers of x and then rewriting those words in terms of the aᵢ:

\[ K = \langle aᵢ \mid aᵢ₊₂⁻¹aᵢ⁺¹aᵢ⁻¹aᵢ, i ∈ Z \rangle \]
We regard the relation $a_{i+2}^{-1}a_{i+1}a_{i+2}^{-1}a_i^2$ as a word $r = r(a_i, a_{i+1}, a_{i+2})$. A representation $\rho : K \to \Sigma$ is a function $\rho$ from the set of generators $a_i$ into $\Sigma$ such that for every $i \in \mathbb{Z}$ the element $r(\rho(a_i), \rho(a_{i+1}), \rho(a_{i+2}))$ is trivial in $\Sigma$. Any such function can be constructed as follows, beginning with Step 0 and proceeding to Steps $\pm 1, \pm 2$, etc.:

(Step $-2$) Choose $\rho(a_{-2})$ if possible such that $r(\rho(a_{-2}), \rho(a_{-1}), \rho(a_0)) = e$.
(Step $-1$) Choose $\rho(a_{-1})$ if possible such that $r(\rho(a_{-1}), \rho(a_0), \rho(a_1)) = e$.
(Step 0) Choose values $\rho(a_0)$ and $\rho(a_1)$.
(Step $+1$) Choose $\rho(a_2)$ if possible such that $r(\rho(a_0), \rho(a_1), \rho(a_2)) = e$.
(Step $+2$) Choose $\rho(a_3)$ if possible such that $r(\rho(a_1), \rho(a_2), \rho(a_3)) = e$.

The process of selecting values $\rho(a_i)$ is accomplished by following any bi-infinite path on a directed graph $\Gamma$. The vertices of $\Gamma$ are maps $\rho_0 : \{a_0, a_1\} \to \Sigma$, each of which can be regarded as an ordered pair $(\rho_0(a_0), \rho_0(a_1))$. There is a directed edge from $\rho_0$ to $\rho_0'$ if and only if (1) $\rho_0(a_1) = \rho_0'(a_0)$ and (2) $r(\rho_0(a_0), \rho_0(a_1), \rho_0'(a_1)) = e$. Conditions
(1) and (2) enable us to extend the function $\rho_0 : \{a_0, a_1\} \to \Sigma$ by defining $\rho_0(a_2)$ to be equal to $\rho_0'(a_1)$. Now if there is an edge from $\rho_0'$ to $\rho_0''$ we can likewise extend $\rho_0$ by defining $\rho_0(a_3)$ to be $\rho_0''(a_1)$. In fact, a bi-infinite path in the graph corresponds to a map from the generating set of $K$ to $\Sigma$ which sends all relators to the identity element, and hence corresponds to a representation of $K$. When $\Sigma$ is abelian, any representation $\rho$ of elements of $\Sigma$ to the generators $\{g, l, a, \ldots\}$ is the complete graph on $\Sigma$. The resulting representation shift consists of all bi-infinite paths in $\Gamma$, and it is also known as the full shift on $\Sigma$. As in the previous example we regard $\rho_0$ as a partial assignment of elements of $\Sigma$ to the generators $a_{i,j}$. There is an edge from $\rho_0$ to $\rho_0'$ if and only if (1) $\rho_0(a_{i,j+1}) = \rho_0'(a_{i,j})$ whenever $a_{i,j}, a_{i,j+1} \in A_0$ and (2) the images of $r_{1,0}, \ldots, r_{n,M_n}$ under the partial assignment are trivial.

**Example 3.3.** Consider the trivial link of two components. The group $G = \pi_1(S^3 - l, *)$ is a free group on meridian generators $x$ and $y$ corresponding to the two components $l_1$ and $l_2$, respectively. We replace $y$ by $xa$ and apply the Reidemeister–Schreier Theorem as we did in Example 3.2 in order to see that the kernel $K$ is the free group generated by $a_i, i \in \mathbb{Z}$. Since there are no nontrivial relations, the directed graph $\Gamma$ describing $\Phi_2(l)$ is the complete graph on $\Sigma$. The resulting representation shift consists of all bi-infinite paths in $\Gamma$, and it is also known as the full shift on $\Sigma$.

**Example 3.4.** Consider the Borromean rings $l = 6_2^3$ oriented as in Figure 5a with Wirtinger generators indicated. The group $G = \pi_1(S^3 - l, *)$ has presentation

$$\langle x, x_1, y, y_1, z, z_1 \mid zx = x_1z, xy = y_1x, yz = z_1y, z_1y_1 = y_1z, z_1z = x_1z_1 \rangle.$$ 

We use the first three relators to eliminate $x_1, y_1$ and $z_1$ from the presentation, obtaining

$$\langle x, y, z \mid yzy^{-1}xyx^{-1} = xyx^{-1}z, zxz^{-1}yzy^{-1} = yzy^{-1}x \rangle.$$ 

We replace $y$ by $xa$ and $z$ by $xb$, and apply the Reidemeister–Schreier method to produce the following presentation for the kernel $K$:

$$K = \langle a_i, b_i \mid a_{i+2}b_{i+1}a_i^{-1}a_{i+1}b_{i+2}^{-1}, b_{i+2}b_{i+1}a_{i+1}b_{i+2}^{-1}a_i^{-1}a_{i+1}b_{i+2}^{-1}a_i^{-1}a_{i+1}b_{i+2}^{-1}, i \in \mathbb{Z} \rangle.$$ 

When $\Sigma$ is abelian, any representation $\rho : K \to \Sigma$ factors through the quotient map.
$K \rightarrow K/[K,K]$. It is clear from the presentation for $K$ that the quotient $K/[K,K]$ decomposes as

$\langle a_i \mid a_{i+2} - 2a_{i+1} + a_i, \ i \in \mathbb{Z} \rangle \oplus \langle b_i \mid b_{i+2} - 2b_{i+1} + b_i, \ i \in \mathbb{Z} \rangle$.

Hence when $\Sigma$ is abelian the representation shift $\Phi_\Sigma(l)$ is a Cartesian product $\Psi \times \Psi$. For example, when $\Sigma = \mathbb{Z}/4$ the graph for $\Psi$ computed from its presentation has eight disjoint cycles: 4 cycles of length 1; 2 cycles of length 2; 2 cycles of length 4. (See Figure 5b.)

**Fig. 5a. The link $l = 6_3^2$**

\[
\begin{align*}
(0,0) & \xrightarrow{\tau} (1,1) & (2,2) & \xrightarrow{\tau} (3,3) \\
(2,0) & \xrightarrow{\alpha, \tau} (0,2) & (1,3) & \xrightarrow{\alpha, \tau} (3,1) \\
(1,0) & \xrightarrow{\alpha, \tau} (0,3) & (3,0) & \xrightarrow{\alpha, \tau} (0,1) \\
(2,1) & \xleftarrow{\alpha, \tau} (3,2) & (2,3) & \xleftarrow{\alpha, \tau} (1,2)
\end{align*}
\]

**Fig. 5b. Graph of $\Psi$**

In Example 3.2 the only fixed point is the trivial representation, and the representation shift is finite. In general, if $k$ is any knot and $\Sigma$ is arbitrary, then the the only fixed point of $\Phi_\Sigma(k)$ will be the trivial representation; if $\Sigma$ is abelian, then the shift will also be finite (see [SiWi2]). These statements need not be true for links, as Examples 3.3 and 3.4 reveal.

**4. Color representations.** Assume that $D$ is a diagram for a knot $k$. It is well known that the $n$-colorings of $D$ correspond to representations of $G = \pi_1(S^3 - k)$ onto the dihedral group $D_n = \langle \alpha, \tau \mid \alpha^n = \tau^2 = e, \ \tau \alpha \tau^{-1} = \alpha^{-1} \rangle$. More precisely, given any $n$-coloring of $D$, we obtain a representation $\overline{\varphi} : G \rightarrow D_n$ by mapping the Wirtinger generator $x_i$ corresponding to the ith arc of $D$ to the element $\tau \alpha^{c_i}$, where $c_i$ is the color of the ith arc. Conversely, any representation $\varphi$ of $G$ onto $D_n$ must map each Wirtinger generator $x_i$ to one of the elements $\tau, \tau \alpha, \ldots, \tau \alpha^{n-1}$ and hence determines an $n$-coloring of $D$. The restriction of such a representation $\overline{\varphi}$ to the commutator subgroup $K$ produces an element $\rho \in \Phi_{\mathbb{Z}/n}(k)$ with the property that $\rho + \sigma x \rho$ is trivial.
DEFINITION 4.1. Let \( l \) be an oriented link and let \( n \) and \( r \) be positive integers with \( r \geq 2 \). An \((n, r)\)-color representation of \( l \) is a representation \( \rho \in \Phi_{\mathbb{Z}/n}(l) \) such that \( \rho + \sigma_x \rho + \ldots + \sigma_x^{r-1} \rho \) is trivial. A color representation is an \((n, r)\)-color representation for some \( n \) and \( r \).

LEMMA 4.2. Every \((n, r)\)-color representation is periodic with period \( r \). If \( k \) is an oriented knot then, conversely, every period \( r \) representation is an \((n, r)\)-color representation.

Proof. If \( \rho + \sigma_x \rho + \ldots + \sigma_x^{r-1} \rho \) is trivial then so is \( \sigma_x (\rho + \sigma_x \rho + \ldots + \sigma_x^{r-1} \rho) = \sigma_x \rho + \ldots + \sigma_x^{r-1} \rho \). Hence \( \sigma_x^r \rho = \rho \).

Conversely, suppose that \( \rho \in \Phi_{\mathbb{Z}/n}(l) \) is a representation such that \( \sigma_x^r \rho = \rho \). Since the representation \( \rho + \sigma_x \rho + \ldots + \sigma_x^{r-1} \rho \) is fixed by \( \sigma_x \), it must be trivial [SiWi2]. Hence \( \rho \) is an \((n, r)\)-color representation. \( \blacksquare \)

For a link \( l \) a period \( r \) representation need not be an \((n, r)\)-color representation, as Examples 3.3 and 3.4 show.

The significance of color representations is contained in the next result.

THEOREM 4.3. Let \( D \) be a diagram for an oriented link \( l \) with a distinguished arc \( \delta \). For each \( n \), the based \((n, r)\)-colorings of \( D \) are in one-to-one correspondence with the \((n, r)\)-color representations \( \rho \in \Phi_{\mathbb{Z}/n}(l) \).

Proof. Suppose that \( \rho : K \to \mathbb{Z}/n \) is a color representation of \( l \). Let \( r \) be the smallest integer \( \geq 2 \) such that \( \rho + \sigma_x \rho + \ldots + \sigma_x^{r-1} \rho \) is trivial. We obtain a based \((n, r)\)-coloring of \( D \) as follows. Assign the trivial color vector \((0, \ldots, 0) \in (\mathbb{Z}/n)^{r-1}\) to the arc \( \delta \) corresponding to the distinguished generator \( x \). Any other arc determines a Wirtinger generator \( x_i \) of the group \( G \) of the link, and the product \( a = x^{-1} x_i \) is contained in \( K \). Assign the color vector \((\rho(a), \ldots, \sigma_x^{r-1} \rho(a)) \) to the arc. Using the Wirtinger relations, it is not difficult to check that our assignment satisfies condition (2.1).

Conversely, suppose we have a based \((n, r)\)-coloring of \( D \) that assigns the vector \((c_{i,0}, \ldots, c_{i,r-2}) \) to the \( i \)th arc. By the Reidemeister–Schreier Theorem, \( K \) is generated by the elements \( x^{-\nu}(x^{-1} x_i) x^\nu \) subject to families of relations corresponding to each crossing of the diagram: a positive crossing (see Figure 2) introduces the family of relations
\[
x^{-\nu}(x_k^{-1} x_i) x^\nu = x^{-\nu}(x_j x_k^{-1}) x^\nu,
\]
or equivalently,
\[
x^{-\nu-1}(x_k^{-1} x_i) x^{\nu+1}, x^{-\nu-1}(x_j^{-1} x_i) x^{\nu+1} = x^{-\nu}(x_k^{-1} x_j) x^\nu \cdot x^{-\nu}(x^{-1} x_k)^{-1} x^\nu,
\]
while a negative crossing introduces
\[
x^{-\nu-1}(x_k^{-1} x_i) x^{\nu+1}, x^{-\nu-1}(x_j^{-1} x_i) x^{\nu+1} = x^{-\nu}(x_k^{-1} x_j) x^\nu \cdot x^{-\nu}(x^{-1} x_k)^{-1} x^\nu.
\]
Condition (2.1) ensures that the mapping
\[
\rho(x^{-\nu}(x^{-1} x_i) x^\nu) = c_{i, \nu} \text{ if } \nu \equiv 0, 1, \ldots, r - 2 \mod r,
\]
\[
\rho(x^{-\nu}(x^{-1} x_i) x^\nu) = -c_{i,0} - \ldots - c_{i,r-2} \text{ if } \nu \equiv r - 1 \mod r
\]
determines a color representation \( \rho \in \Phi_{\mathbb{Z}/n}(l) \). If we assume that the \((n, r)\)-coloring with which we began is not an extension in the sense of Proposition 2.3 of any \((n, r')\)-coloring.
with $r'$ a proper factor of $r$, then by applying the procedure in the first half of the proof we recover that coloring. Hence the theorem is proved.}$

Just as $n$-colorings of a diagram for a knot correspond to dihedral representations of the group $G$ of the knot, the more general $(n,r)$-colorings correspond to certain metabelian representations of $G$. We have chosen the symbolic dynamical approach in favor of the more algebraic one for two reasons. First, as R. Hartley has noted in [Ha], the complicated structure of the Alexander module forbids a complete algebraic analysis. Second, the dynamical approach is constructive and often comparatively simple.

**Example 4.4.** Consider the 3-component link $l = 6^3_1$ oriented as in Figure 6a with Wirtinger generators indicated. The group $G$ of the link has presentation

\[ \langle x, x_1, y, y_1, z, z_1 \mid y_1z = zy, z_1x = xz, x_1y = yx, x_1y_1 = yx_1, zy_1 = y_1z_1 \rangle. \]

Using the first three relators we can eliminate the generators $x_1, y_1$ and $z_1$ from the presentation, obtaining

\[ \langle x, a, b \mid xy^{-1}zyz^{-1}yx^{-1}y^{-1}, zyz^{-1}xzx^{-1}x^{-1}zy^{-1} \rangle. \]

We apply the same steps as in Example 3.2 in order to present the kernel $K$ of the total linking homomorphism.

\[ K = \langle a_i, b_i \mid a_i a_{i+2}^{-1} b_i b_{i+1}^{-1}, b_i^{-2} b_{i+1} a_i^{-1} b_{i+1} a_i, i \in \mathbb{Z} \rangle. \]

If we are interested in the $(3,3)$-colorings of a diagram for $l$, then we can allow the generators $a_i, b_i$ to commute and reduce all coefficients modulo 3 (i.e., replace $K$ by its abelianization tensored with $\mathbb{Z}/3$). When we do this the two families of relations become

\[-a_i + a_{i+1} - b_i + b_{i+1}, \quad a_i - a_{i+1} + b_i - b_{i+1}.\]

Clearly the second family is a consequence of the first. Moreover, the first relations can be rewritten as $b_{i+1} = a_i - a_{i+1} + b_i$. We can construct all homomorphisms $\rho$ from $K$ to $\mathbb{Z}/3$ by mapping the generators $a_i, b_0$ arbitrarily; the images of the remaining generators $b_i, i \neq 0$, are then determined by the relations. (The graph $\Gamma$ that describes $\Phi_{\mathbb{Z}/3}$ consists of three disjoint complete directed graphs - each component corresponding to a choice for the image of $b_0$. See [SiWi2].) In order to determine the based $(3,3)$-coloring corresponding to any $(3,3)$-color representation, we must first express $x^{-1}y$, $x^{-1}z$, $x^{-1}x_1$, $x^{-1}y_1$, and $x^{-1}z_1$ in terms of the generators $a_i, b_i$. An easy computation reveals

\[ x^{-1}y = a_0, \quad x^{-1}z = b_0, \quad x^{-1}x_1 = a_0 - a_{-1}, \]

\[ x^{-1}y_1 = a_{-1} - b_{-1} + b_0, \quad x^{-1}z_1 = b_{-1}. \]

If $\alpha$ and $\beta$ are elements of $\mathbb{Z}/3$, then the mapping $\rho : K \to \mathbb{Z}/3$ that sends each generator $a_i$ to $\alpha$ and each $b_i$ to $\beta$ is a $(3,3)$-color representation, a fixed point in the shift $\Phi_{\mathbb{Z}/3}(l)$. From our computation we see that $\rho$ corresponds to a based $(3,3)$-coloring of our diagram in which the $y$-arc is colored by $(\rho(a_0), \rho(a_1)) = (\alpha, \alpha)$ while the $z$-arc is colored by $(\rho(b_{-1}), \rho(b_0)) = (\beta, \beta)$, etc. Figure 6b contains the based coloring.

The shift $\Phi_{\mathbb{Z}/3}(l)$ also contains $(3,3)$-color representations that are not fixed points. One such representation is determined by

\[ a_{3i} \mapsto 1, \quad a_{3i+1} \mapsto 0, \quad a_{3i+2} \mapsto 2, \]
The corresponding based \((3, 3)\)-coloring is shown in Figure 6c.

Now consider the oriented link \(l'\) obtained from \(l\) by reversing the orientation of the component containing the arc \(\delta\). Repeating the steps above we discover that the kernel \(K\) abelianized has a new presentation

\[
\langle a_i, b_i \mid -a_i + 2a_{i+1} - a_{i+2} - b_{i+1} + b_{i+2}, -a_i + a_{i+1} + b_i - 2b_{i+1} + b_{i+2}\rangle,
\]

where \(i\) ranges over the integers. Reducing the coefficients modulo 3 produces the relations

(R1) \[ a_i + a_{i+1} + a_{i+2} + b_{i+1} - b_{i+2}, \]

(R2) \[ -a_i + a_{i+1} + b_i + b_{i+1} + b_{i+2}. \]

Any \((3, 3)\)-color representation \(\rho\) must vanish on \(a_i + a_{i+1} + a_{i+2}\) and \(b_i + b_{i+1} + b_{i+2}\). However, from relations (R1) and (R2) we see that \(\rho\) must also vanish on \(-a_i + a_{i+1}\) and \(b_{i+1} - b_{i+2}\). Consequently, \(\rho\) must be a fixed point of the shift \(\Phi_{\mathbb{Z}/3}(l')\). This means that \(\text{col}_{3,3}(l') \neq \text{col}_{3,3}(l)\).
Example 3.2 revisited. The diagram for the knot \( k = 5_2 \) has 6 nontrivial based \((7,2)\)-colorings corresponding to the 6 nontrivial representations of period 2. It has 48 nontrivial based \((7,14)\)-colorings corresponding to the 48 nontrivial representations of period 14. Figure 7 displays the based \((7,2)\)-coloring that corresponds to the representa-

![Diagram](image)

**Fig. 7.** Based \((7,2)\)-coloring of \( 5_2 \)

</tr>
</tbody>
</table>

From this we see that if \( \delta \) is colored 0, then the arc corresponding to \( x_2 \) is colored \( \rho(a_0) = 5 \). Likewise, the arc corresponding to \( x_3 \) is colored 3, etc.

**Fig. 8.** Based \((4,2)\)-colorings of \( 6_2^3 \)
Example 3.4 revisited. \( \Phi_{Z/4}(l) \) has 256 representations: 16 representations with period 1 (fixed points); 48 representations of least period 2; 192 representations of least period 4. For example, the representations with least period 2 have the form \( (\psi_1, \psi_2) \in \Psi \times \Psi = \Phi_{Z/4}(l) \) where \( \psi_1, \psi_2 \) have periods 1 or 2, but they do not both have period 1. None of the representations of least period 2 is a \( (4,2) \)-color representation. However, fixed points also have period 2 (although not least period 2), and \( \Phi_{Z/4}(l) \) contains 4 fixed points that are \( (4,2) \)-color representations. These representations have the form \( (\psi_1, \psi_2) \) where \( \psi_1, \psi_2 \) correspond to the 1-cycles \( (0,0) \to (0,0) \) and \( (2,2) \to (2,2) \) in \( \Gamma \). The resulting based \( (4,2) \)-colorings are shown in Figure 8.

5. \( (n,r) \)-colorings of satellite knots. If \( \hat{k} \) is a knot that is contained in a solid torus then knotting the solid torus will convert \( \hat{k} \) to a more complicated knot \( k \) called a satellite knot. The idea was introduced by H. Schubert [Sc]. More precisely, assume that \( \hat{k} \) is contained in a standard solid torus \( V \) in \( S^3 \), but not contained in any 3-ball in \( V \). Assume that \( \hat{k} \) is a nontrivial second knot, and let \( f : V \to V(\hat{k}) \) be a diffeomorphism from \( V \) onto a closed tubular neighborhood of \( \hat{k} \), mapping a longitude of \( \tilde{V} \) onto a longitude of the knot \( \hat{k} \). (A longitude of \( \hat{k} \) is an essential simple closed curve in the boundary of \( V(\hat{k}) \) that is nullhomologous in the complement of \( \hat{k} \).) The image \( k = f(\hat{k}) \) is a nontrivial knot, a satellite knot with companion knot \( \hat{k} \) and pattern \( (V, \hat{k}) \). The solid torus \( \tilde{V} \) has infinite cyclic first homology, and the class of \( \hat{k} \) generates a subgroup \( d \cdot H_1(\tilde{V}) \) for some nonnegative integer \( d \). We call \( d \) the winding number of the satellite knot. (See [BuZi] or [Ro].) In the special case that \( \hat{k} \) is a torus knot in the boundary of a smaller solid torus \( V_1 \subset \tilde{V} \) sharing a common core circle with \( V \) the satellite knot \( k \) is also called a cable of \( \hat{k} \). If \( \hat{k} \) is the result of tying a knot in the core circle of \( V \) locally (i.e., in a small 3-ball in \( \tilde{V} \)), then the satellite knot \( k \) is just the connected sum of \( \hat{k} \) and \( k \).

Let \( K, \hat{K} \) and \( \hat{K} \) be the respective commutator subgroups of the groups of \( k, \hat{k} \) and \( \hat{k} \). It can be seen from work of Seifert [Sc] that the abelianization \( K/[K,K] \) is isomorphic to the direct sum of \( \hat{K}/[\hat{K}, \hat{K}] \) and \( d \) copies of \( K/[K,K] \). Moreover, if \( x, \hat{x} \) and \( \hat{x} \) denote respective classes of meridians of \( k, \hat{k} \) and \( \hat{k} \), then conjugation by \( x \) in the group of \( k \) induces an automorphism of \( K/[K,K] \) that maps \( a \in K/[K,K] \) to \( \hat{x}^{-1}a\hat{x} \) and maps \( (a_0, \ldots, a_{d-1}) \in K/[K,K] \oplus \ldots \oplus K/[K,K] \) to \( (a_1, \ldots, a_{d-1}, \hat{x}^{-1}a_0\hat{x}) \). Explicit proofs of these statements can be found in [LvMe].

We conclude with a theorem that demonstrates the power of symbolic dynamical techniques.

Theorem 5.1. Assume that \( k \) is a satellite knot with companion knot \( \hat{k} \), pattern knot \( \hat{k} \) and winding number \( d \). Let \( n \) and \( r \) be positive integers with \( r \geq 2 \).

If \( d = 0 \), then \( \text{col}_{n,r}^0(k) = \text{col}_{n,r}^0(\hat{k}) \).

If \( d \neq 0 \), then \( \text{col}_{n,r}^0(k) = \text{col}_{n,r}^0(\hat{k}) \cdot [\text{col}_{n,r}^0(\hat{k})]^q \), where \( q = \gcd(d, r) \).

Theorem 5.1 follows from the above comments and a general result about dynamical systems that we describe now. Assume that \( (\hat{\Phi}, \hat{\sigma}) \) and \( (\hat{\Phi}, \hat{\sigma}) \) are two dynamical systems. Given any positive integer \( d \) we define a satellite dynamical system \( (\Phi, \sigma) \) such that \( \Phi = \hat{\Phi} \times \ldots \times \hat{\Phi} \) (\( d \) copies of \( \hat{\Phi} \)), and \( \sigma(p, \tau_0, \ldots, \tau_{d-1}) = (\hat{\sigma}p, \tau_1, \ldots, \tau_{d-1}, \hat{\tau}_0) \). Recall that \( \text{Fix} \) denotes the set of fixed points of the automorphism \( f \).
Proposition 5.2. Assume that \((\Phi, \sigma)\) is the satellite dynamical system determined by \((\hat{\Phi}, \hat{\sigma}), (\Phi, \hat{\sigma})\) and positive integer \(d\). Then for any positive integer \(r\),
\[
|\text{Fix } \sigma^r| = |\text{Fix } \hat{\sigma}^r| \cdot |\text{Fix } \hat{\sigma}^{rd/q}|^q,
\]
where \(q = \gcd(d, r)\).

Proof. Let \(\phi = (\rho, \tau_0, \ldots, \tau_{d-1}) \in \text{Fix } \sigma^r\). Clearly \(\rho \in \text{Fix } \hat{\sigma}^r\). Also,
\[
\phi = \sigma^{rd/q}\phi = (\hat{\sigma}^{rd/q}\rho, \hat{\sigma}^{rd/q}\tau_0, \ldots, \hat{\sigma}^{rd/q}\tau_{d-1}),
\]
so \(\tau_i \in \text{Fix } \hat{\sigma}^{rd/q}\) for all \(i\). We can write \(mr = nd + q\) for some positive integers \(m\) and \(n\), so \(\phi = \sigma^{mr}\phi = \sigma^{nd+q}\phi\). This gives
\[
(5.1) \quad \tau_i = \hat{\sigma}^{n\tau_i+q}, \quad 0 \leq i \leq d - q - 1.
\]

Thus \(\tau_0, \ldots, \tau_{q-1}\) uniquely determine \(\tau_q, \ldots, \tau_{d-1}\), which in turn uniquely determine \(\tau_{2q}, \ldots, \tau_{aq-1}\) and so on. Conversely, given \(\rho\) in \(\text{Fix } \hat{\sigma}^r\) and \(\tau_0, \ldots, \tau_{q-1}\) in \(\text{Fix } \hat{\sigma}^{rd/q}\), we can use (5.1) to define \(\tau_q, \ldots, \tau_{d-1}\), so that \(\phi = (\rho, \tau_0, \ldots, \tau_{d-1})\) is in \(\text{Fix } \sigma^r\). \(\blacksquare\)

Let \(D\) be a diagram for an oriented knot \(k\). We have remarked previously that for any positive integers \(n, r\) with \(r \geq 2\) the based \((n, r)\)-colorings of \(D\) form a module over \(\mathbb{Z}/n\). In [SiWi2] we showed that \(\text{Fix } \sigma^r_x\) is isomorphic to \(H_1(M_r(k); \mathbb{Z}/n)\), where \(M_r(k)\) is the \(r\)-fold branched cyclic cover of \(k\) (see [BuZi] or [Ro]). The following reformulation of Theorem 5.1 is a consequence.

Theorem 5.3 [Li], [LvMe]. Assume that \(k\) is a satellite knot with companion knot \(\hat{k}\), pattern knot \(\hat{k}\) and winding number \(d\). Let \(n\) and \(r\) be positive integers with \(r \geq 2\), and \(q = \gcd(d, r)\).

If \(d = 0\), then \(H_1(M_r(k); \mathbb{Z}/n) \cong H_1(M_r(\hat{k}); \mathbb{Z}/n)\).

If \(d \neq 0\), \(H_1(M_r(k); \mathbb{Z}/n) \cong H_1(M_r(\hat{k}); \mathbb{Z}/n) \oplus [H_1(M_r(\hat{k}); \mathbb{Z}/n)]^q\).
