On Polish spaces Lipschitz universal for separable metric spaces

by

P. Mankiewicz (Warszawa)

Abstract. It is proved that a separable complete metric space which is Lipschitz universal for all separable reflexive Banach spaces is Lipschitz universal for all separable metric spaces.

1. Introduction. L. Aharoni [1] proved that the Banach space $C(0, 1)$ can be Lipschitz embedded into the Banach space $c_0$ (the space of all real-valued sequences converging to zero). This, combined with the Kuratowski–Wojdyslawski Theorem [3], implies that the Banach space $c_0$ is Lipschitz universal for all separable metric spaces [1]. In other words, a separable metric space is Lipschitz universal for all separable metric spaces if and only if it Lipschitz-contains $c_0$. The aim of this note is to prove that if a complete separable metric space $(M, \rho)$ is Lipschitz universal for all separable reflexive Banach spaces then $(M, \rho)$ Lipschitz contains $c_0$ and therefore is Lipschitz universal for all separable metric spaces. This means that the class of Lipschitz structures of separable reflexive Banach spaces is rich — "it spans" all possible separable Lipschitz structures. But, on the other hand, the Lipschitz structures of reflexive Banach spaces are "specific" — not every metric space can be Lipschitz embedded into a reflexive Banach space. More precisely, it is known [7] that if a Banach space $X$ is Lipschitz embeddable into a reflexive Banach space then $X$ is reflexive as well.

The proof presented in this note is based on H. P. Rosenthal's [9] version of the proof of the following result due to J. Bourgain [4]: A separable Banach space which is isomorphically universal for all separable reflexive Banach spaces is isomorphically universal for all separable Banach spaces.

2. Preliminaries. Let $(M, \rho)$ and $(N, h)$ be metric spaces. A map $r : M \to N$ is said to be a Lipschitz embedding of $M$ into $N$ iff there are positive constants $K$ and $k$ such that

$$k\rho(x, y) \leq h(r(x), r(y)) \leq K\rho(x, y) \quad \text{for all } x, y \in M.$$
We say that a metric space \((M, \rho)\) is Lipschitz universal for a class of metric spaces \(A\) iff every metric space from the class \(A\) is Lipschitz embeddable into \((M, \rho)\).

Let \(\prec\) be an order relation on an arbitrary set \(T\). The order relation \(\prec\) is said to be well founded iff every subset \(A\) of \(T\) admits a maximal element in \(A\) with respect to the order relation \(\prec\) restricted to \(A\). The set of all such elements will be denoted by \(\text{Max}(A)\). Set \(H_\beta(T) = T\) and assume that \(H_\beta(T)\) for all ordinals \(\alpha < \beta\) have been defined. Then, if \(\beta\) is a limit ordinal, we define \(H_\beta(T) = \bigcap \{H_\alpha(T) \mid \alpha < \beta\}\). Otherwise, i.e. if \(\beta = \alpha_0 + 1\) for some ordinal \(\alpha_0\), we define \(H_\beta(T) = H_{\alpha_0}(T) \setminus \text{Max}(H_{\alpha_0}(T))\). Since \(\prec\) is well founded we infer that \(H_\beta(T)\)'s are strictly decreasing and therefore eventually are empty sets. The smallest \(\alpha\) such that \(H_\alpha(T)\) is an empty set is called the index of the well-founded ordered set \((T, \prec)\) and will be denoted by \(\text{Ind}(T, \prec)\). In the sequel we shall need the following well-known result, cf. [5].

**Theorem 1.** (Kunen–Martin Theorem). The index of a well-founded analytic order relation on a separable complete metric space is a countable ordinal.

Using standard transfinite induction, one can easily prove

**Proposition 2.** Let \((T_1, \prec_1)\) and \((T_2, \prec_2)\) be well-founded ordered sets and let \(\varphi: T_1 \rightarrow T_2\) be an order-preserving mapping. Then for each ordinal \(\alpha\) we have

\[ \varphi(H_\alpha(T_1)) \subseteq H_\alpha(T_2) \]

and consequently \(\text{Ind}(T_1, \prec_1) \leq \text{Ind}(T_2, \prec_2)\).

The smallest uncountable ordinal will be denoted by \(\omega\).

3. Lipschitz \(\omega\)-indices of separable complete metric spaces. By \(c_0\) we shall mean the Banach space of all bounded sequences converging to zero endowed with its standard supremum norm. For every \(n \in \mathbb{N}\) we set

\[ A_n = \{\lambda_i \mid i \in \mathbb{N}, |\lambda_i| \leq 2^n \} \text{ for } 1 \leq i \leq 2^n \text{ and } \lambda_0 = 0 \text{ otherwise} \].

For every separable complete metric space \((M, \rho)\) and every \(n, m \in \mathbb{N}\) we define \(T_{n,m}(M, \rho)\) to be the set of all Lipschitz mappings \(t: A_n \rightarrow M\) satisfying

\[ \|t(a) - t(b)\| \leq \|t(a) - t(b)\| \leq m\|a - b\| \text{ for } a, b \in A_n \]

endowed with the sup-metric. It is clear that for every \(n, m \in \mathbb{N}\), the space \(T_{n,m}(M, \rho)\) is a complete separable metric space. For every \(m \in \mathbb{N}\), let

\[ T_n(M, \rho) = \bigoplus_{m=1}^{\infty} T_{n,m}(M, \rho) \]

be the discrete union of the corresponding \(T_{n,m}\)’s. Obviously, \(T_n(M, \rho)\) is a separable complete-metrizable space. Now, for every \(m \in \mathbb{N}\) define the order relation \(\prec_m\) on \(T_n(M, \rho)\) in the following way: for \(t_1, t_2 \in T_n(M, \rho)\) we say that \(t_1 \prec_m t_2\) iff \(t_1 \subseteq t_2\) \& \(t_1 \in T_{n_1,m}(M, \rho)\) \& \(t_2 \subseteq T_{n_2,m}(M, \rho)\) with \(n_1 < n_2\) and \(t_1\) is equal to \(t_2\) restricted to \(A_{n_1}\). Trivially, \(\prec_m\) is a closed relation. In the sequel we shall need

**Proposition 3.** A separable complete metric space \((M, \rho)\) Lipschitz contains \(c_0\) if and only if for some \(m \in \mathbb{N}\) the relation \(\prec_m\) on \(T_n(M, \rho)\) is not well founded.

**Proof.** Let \(f\) be a Lipschitz embedding of \(c_0\) into a separable complete metric space \((M, \rho)\) such that (1) holds for some \(0 < k < K\). Then \(f(x) = f(kx)\) is a Lipschitz embedding of \(c_0\) into \((M, \rho)\) satisfying (2) for every positive integer \(m \geq k^{-1}K\). Fix such an \(m\) and set \(t_n = f(A_n)\) for \(n \in \mathbb{N}\). Since \(t_n \subseteq T_{n,m}(M, \rho)\) for every \(n \in \mathbb{N}\) and \(t_{n_1} \prec_m t_{n_2}\) for every \(n_1 < n_2\), we infer that the set \(\{t_n \mid n \in \mathbb{N}\}\) is not maximal element. Thus \((T_n(M, \rho), \prec_m)\) is not well-founded.

Conversely, if for some \(m \in \mathbb{N}\) the ordered set \((T_n(M, \rho), \prec_m)\) is not well-founded, then there is a sequence \((t_n)_{n=1}^{\infty} \subseteq T_n(M, \rho)\) such that \(t_{n_1} \prec_m t_{n_2}\) for every \(n_1 < n_2\). Setting \(\tau = \lim t_n\), we obtain a Lipschitz embedding of \(\bigcup_{n=1}^{\infty} A_n \subseteq c_0\) into \((M, \rho)\) satisfying (2). Since \(\bigcup_{n=1}^{\infty} A_n\) is dense in \(c_0\), the map \(f\) admits an unique extension to a Lipschitz embedding \(f\) of \(c_0\) into \((M, \rho)\) satisfying (2), which completes the proof.

Note that for every separable complete metric space \((M, \rho)\), if \(m_1 < m_2\) then \(T_{n,m_1}(M, \rho) \subseteq T_{n,m_2}(M, \rho)\) and \(\prec_{m_1}\) is equal to \(\prec_{m_2}\) restricted to \(T_{n,m_1}(M, \rho)\). Thus, by Propositions 2 and 3, if \((M, \rho)\) does not contain \(c_0\), then

\[ \text{Ind}(T_{n,m}(M, \rho), \prec_m) \leq \text{Ind}(T_{n,m_2}(M, \rho), \prec_{m_2}) \]

and therefore \(\lim_{n \to \infty} \text{Ind}(T_n(M, \rho), \prec_\infty)\) exists.

For every separable complete metric space \((M, \rho)\) which does not Lipschitz contain \(c_0\), we define

\[ \text{ind}(M, \rho) = \lim_{n \to \infty} \text{Ind}(T_n(M, \rho), \prec_\infty) \]

If such a space Lipschitz contains \(c_0\), we set

\[ \text{ind}(M, \rho) = \omega_1 \]

**Proposition 4.** The function \(\text{ind}\) defined on the class of all separable complete metric spaces has the following properties:

(i) \(\text{ind}(M, \rho) \leq \omega_1\) for every separable complete metric space \((M, \rho)\),

(ii) \(\text{ind}(M, \rho) = \omega_1\) if and only if \((M, \rho)\) Lipschitz contains \(c_0\),

(iii) if there is a Lipschitz embedding \(f\) of \((M, \rho)\) into \((N, h)\) such that

\[ \rho(x, y) \leq h(f(x), f(y)) \leq K\rho(x, y) \quad \text{for } x, y \in M, \]
then
\[ \text{ind}(M, q) \leq \text{ind}(N, h). \]

Proof. (i) (ii) If \((M, q)\) Lipschitz contains \(c_0\), then, by definition,
\[ \text{ind}(M, q) = \omega_1. \] If \((M, q)\) does not contain \(c_0\), then for each \(m \in \mathbb{N}\), the order relation \(\prec_m\) on \(T_m(M, q)\) is, by Proposition 3, well founded. Since \(\prec_m\) is closed, by the Kunen–Martin Theorem we conclude that \(\text{ind}(T_m(M, q), \prec_m) < \omega_1\) for every \(m \in \mathbb{N}\), and therefore \(\lim_{m \to \infty} \text{ind}(T_m(M, q), \prec_m) < \omega_1\).

(iii) If \((N, h)\) Lipschitz contains \(c_0\), then (iii) follows from (i) and (ii).
Assume that \((N, h)\) does not Lipschitz contain \(c_0\) and fix a positive integer \(m_0 \geq K_F\). Observe that, for every \(m \in \mathbb{N}\), the map \(\varphi_m: T_m(M, q) \to T_{m_0}(N, h)\) defined by \(\varphi_m(t) = \varphi(t)\) is order preserving. Thus, by Proposition 2,
\[ \text{ind}(T_m(M, q), \prec_m) \leq \text{ind}(T_{m_0}(N, h), \prec_{m_0}). \]
Consequently,
\[ \text{ind}(M, q) = \lim_{m \to \infty} \text{ind}(T_m(M, q), \prec_m) = \text{ind}(N, h). \]

4. Construction of separable reflexive Banach space with large Lipschitz \(c_0\)-indices. Since \(c_0\) is not Lipschitz embeddable into a reflexive Banach space \([7]\), by Proposition 4 (ii) we infer that \(\text{ind}(R, ||||) < \omega_1\) for every separable reflexive Banach space \((R, ||||)\). In the proof of the lemma below we shall give, for every countable ordinal \(\alpha\), a construction of a separable reflexive Banach space \((R_\alpha, ||||)\) with \(\text{ind}(R_\alpha, ||||) = \alpha_1 = \omega_1\). To this end, let \(e_\lambda = (1, 0, 0, \ldots) \in c_0\) and let, for a Banach space \((R, ||||)\), let
\[ S_\alpha(R) = \{ t \in T_\alpha(R, ||||) : \langle \lambda, e_\lambda \rangle = \langle t, e_\lambda \rangle \text{ for } -1 \leq \lambda \leq 1 \}
\]
be the restriction of \(<_1\) to the set \(S(R)\).

Lemma 5. For every \(\alpha < \omega_1\), there is a separable reflexive Banach space \((R_\alpha, ||||)\) with \(\text{ind}(S(R_\alpha), <_\alpha) > \alpha\).
Proof (by transfinite induction). Set \((R_\alpha, ||||) = (R, ||||)\) and assume that for every \(\gamma < \alpha\) a separable reflexive Banach space \((R_\gamma, ||||)\) with \(\text{ind}(S(R_\gamma), <_\gamma) > \gamma\) has been defined.

Case 1. \(\alpha\) is the successor of \(\beta\). Define \(R_{\alpha+1} = R_\alpha \times R_\beta\) and \(\| (x, y) \|_{||||} = \max \{ \| x \|_{||||}, \| y \|_{||||} \} \) for \((x, y) \in R_\alpha \times R_\beta\). It is clear that \((R_{\alpha+1}, ||||)\) is a separable reflexive Banach space. Since \(\text{ind}(S(R_{\alpha+1}), <_{\alpha+1}) > \beta\), by definition, we have \(H_{\beta}(S(R_{\alpha+1})) \neq \emptyset\). Let \(t_0 \in H_{\beta}(S(R_{\alpha+1}))\). It follows from the definition of \(<_<\) that \(t_0 = t_0^* a_i \in H_{\beta}(S(R_{\alpha+1}))\). Now, for \(n = 1, 2, \ldots\) define \(\varphi_n: S(R_{\alpha+1}) \to S_{\alpha+1}(R_{\alpha+1})\) by the formula
\[ \varphi_n(t)(a) = 2a \langle (1, a_0, 0, \ldots), 2a_0, (1, a_0, 0, \ldots) \rangle \]
for \(a = (a_0, a_1, \ldots) \in A_{\alpha+1}\) and \(t \in S(R_{\alpha+1})\). It can easily be checked that the mapping \(\varphi\) defined by \(\varphi(t) = \varphi_n(t)\) for \(t \in S(R_{\alpha+1})\) is an order-preserving mapping from \(S(R_{\alpha+1})\) into \(S(R_{\alpha+1})\). Thus, by Proposition 2, \(\varphi(H_{\beta}(S(R_{\alpha+1}))) \subseteq H_{\beta}(S(R_{\alpha+1}))\) and therefore \(\varphi(t_0) \in S_{\alpha+1}(R_{\alpha+1})\). Hence \(t_0 = \varphi(t_0) \in S_{\alpha+1}(R_{\alpha+1})\). Thus \(H_{\beta}(S(R_{\alpha+1})) \neq \emptyset\) and therefore \(\text{ind}(S(R_{\alpha+1}), <_{\alpha+1}) > \beta\), which completes the proof in case 1.

Case 2: \(\alpha\) is a limit ordinal. By the induction hypothesis, \(H_{\beta}(S(R_\beta)) \neq \emptyset\) for every \(\beta < \alpha\). For every \(\gamma < \alpha\) select \(t_\gamma \in H_{\beta}(S(R_\beta))\) and set \(t_\gamma = t_\gamma a_1\). Obviously, \(t_\gamma \in H_{\beta}(S(R_\beta))\) for every \(\gamma < \alpha\). By (4), for every \(\gamma < \alpha\) there is an \(x_\gamma \in R_\gamma\) with \(\| x_\gamma \|_{||||} = 1\) such that \(t_\gamma(x_\gamma) = \lambda x_\gamma\) for \(-1 < \lambda < 1\). Let
\[ R_\beta = \{ (\mu(x_\gamma x_\gamma + (y_\gamma y_\gamma) x_\gamma) : \gamma < \alpha, \mu \in R_\alpha, y_\gamma \in R_\gamma, \text{ and } \sum_{\gamma < \alpha} \| y_\gamma \|_{||||}^2 < \infty \} \]
equipped with the norm
\[ \| \mu(x_\gamma x_\gamma + (y_\gamma y_\gamma) x_\gamma) \|_{||||} = \max \{ \sup_{\gamma < \alpha} \| \mu x_\gamma + y_\gamma x_\gamma \|, (\sum \| y_\gamma \|_{||||}^2)^{1/2} \}. \]
Since \((R_\beta, ||||)\) is a one-dimensional enlargement of the \(\ell_2\)-sum of \(R_\beta\), it is obvious that \((R_\beta, ||||)\) is a separable reflexive Banach space. Fix an arbitrary \(\beta < \alpha\) and, for \(\alpha < \omega_1\), define
\[ \varphi_\alpha(t)(a) = (a_0, (x_\alpha x_\alpha + t (a_0)^2) - a_0 x_\alpha) \]
for \(t \in S(R_\beta)\) and \(a = (a_0, a_1, \ldots) \in A_\beta\). Note that, for \(\alpha < \omega_1\), \(\varphi_\alpha(R_\beta) \neq \emptyset\) and \(a, b \in A_\beta\) with \(a = (a_0, a_1, \ldots), b = (b_1, b_2, \ldots)\) we have
\[ \| a x_\beta - b x_\beta \|_{||||} = |a_1 - b_1| < \| a - b \| \]
for every \(\gamma \neq \beta, \gamma < \alpha\), and
\[ \| a x_\beta + t (a_{\beta}) - a x_\beta \|_{||||} = \| b x_\gamma + t (b_{\gamma}) - b x_\gamma \|_{||||} = \| (t (a) - t (b)) x_\gamma \|_{||||} = \| a - b \| \]
and
\[ \| (t (a) - a x_\beta) - (t (b) - b x_\beta) \|_{||||} < \| (t (a) - t (b)) x_\gamma \|_{||||} + |a_1 - b_1| \leq 2 \| a - b \| \]
Hence
\[ \| \varphi_\beta(t)(a) - \varphi_\beta(t)(b) \|_{||||} = \| a - b \| \]
for \(a, b \in A_\beta, a, b \in A_\beta\) and \(t \in S_\beta(R_\beta)\). On the other hand, it follows from (4) and (5) that \(\varphi_\beta(t)\) restricted to the interval \([-e_\lambda, e_\lambda]\) is linear. This and (6) imply
that \( \varphi \) maps \( S(R) \) into \( S(R_n) \) for \( n \in \mathbb{N} \). Define \( \varphi(t) = \varphi(t) \) for \( t \in S(R_n) \) and \( n \in \mathbb{N} \). It easily follows from (5) that \( \varphi \) is an order-preserving mapping from \( (S(R), \prec) \) into \( (S(R_n), \prec) \). By Proposition 2, we infer that \( \varphi(\tilde{t}) \in H(R_n) \). But

\[
\varphi(\tilde{t}) = \lambda \varphi(\tilde{t}_1) = \lambda (x(n)) < n \quad \text{for} \quad -1 \leq \lambda \leq 1.
\]

Since \( \beta \) was an arbitrary ordinal smaller than \( \alpha \), we conclude that for each \( \beta < \alpha \), the map \( t \) defined by

\[
\tilde{t}(x(n)) = \lambda (x(n)) < n \quad \text{for} \quad -1 \leq \lambda \leq 1.
\]

belongs to the set \( H(R_n) \) and therefore \( \tilde{t} \in \cap \bigcup_{k=2}^{\infty} H_k(S(R_n)) = H_\alpha(S(R_n)) \).

Thus \( \text{Ind}(S(R_n), \prec) > \alpha \), which completes the proof.

Lemma 5 yields

**Proposition 6.** For each \( \alpha < \omega_1 \), there is a separable reflexive Banach space \( (R_\alpha, \| \|_\alpha) \) with \( \text{ind}(R_\alpha, \| \|_\alpha) > \alpha \).

**Proof.** For each \( \alpha < \omega_1 \), let \( (R_\alpha, \| \|_\alpha) \) be the space constructed in Lemma 5. Since \( S(R_\alpha) \subseteq T_\alpha(R_\alpha, \| \|_\alpha) \) and \( \lambda < \text{Ind}(S(R), \prec) \), it is clear that \( \text{Ind}(T_\alpha(R_\alpha, \| \|_\alpha) < \alpha \).

On the other hand, \( \text{Ind}(T_\alpha(R_\alpha, \| \|_\alpha) < \alpha \) is a nondecreasing function of \( m \).

Thus

\[
\alpha < \text{Ind}(T_\alpha(R_\alpha, \| \|_\alpha) < \alpha \) \leq \lim_{m \to \infty} \text{Ind}(T_\alpha(R_\alpha, \| \|_\alpha) < \alpha) = \text{ind}(R_\alpha, \| \|_\alpha).
\]

5. Main result and open problems. The main result of this note is the following

**Theorem 7.** For a separable complete metric space \( (M, \varphi) \) the following conditions are equivalent:

(i) \( (M, \varphi) \) is Lipschitz equivalent to \( \varepsilon_0 \).
(ii) \( (M, \varphi) \) is Lipschitz universal for all separable metric spaces.
(iii) \( (M, \varphi) \) is Lipschitz universal for all separable reflexive Banach spaces.

**Proof.** The implication (i) \( \Rightarrow \) (ii) is due to Aharoni [1] and the implication (ii) \( \Rightarrow \) (iii) is trivial. In order to prove that the implication (iii) \( \Rightarrow \) (i) holds, let \( (M, \varphi) \) be a separable complete metric space Lipschitz universal for all separable reflexive Banach spaces. Fix an arbitrary \( \alpha < \omega_1 \) and let \( \tilde{t} \) be the Lipschitz embedding of \( (R, \| \|_\alpha) \) from Proposition 6 into \( (M, \varphi) \) satisfying (1) for some \( 0 < k \leq K \). Set \( f(x) = \tilde{t}^{-1}(x) \) for \( x \in R_\alpha \). Obviously, \( f \) satisfies (3) with \( K_f = k^{-1} \). By Proposition 4 (ii),

\[
\alpha < \text{ind}(R_\alpha, \| \|_\alpha) \leq \text{ind}(M, \varphi).
\]

Since \( \alpha \) was an arbitrary countable ordinal, by Proposition 4 (i), \( \text{ind}(M, \varphi) = \varepsilon_0 \), Finally, by Proposition 4 (ii), the space \( (M, \varphi) \) Lipschitz contains \( \varepsilon_0 \), which completes the proof.

**Remark.** It follows from Aharoni’s result that if \( (M, \varphi) \) is Lipschitz contains \( \varepsilon_0 \), then there is a universal constant \( K_M \) such that for every separable metric space \( (N, h) \) there is a Lipschitz embedding \( f \) of \( N \) into \( M \) with

\[
h(x, y) < \varphi(f(x), f(y)) \leq K_M h(x, y) \quad \text{for all} \quad x, y \in N.
\]

It follows from the argument presented above and from the construction of H. P. Rosenthal [9] that the following version of the Kuratowski-Wojdyslawski Theorem holds:

**Theorem 8.** For a separable complete metric space \( (M, \varphi) \) the following conditions are equivalent:

(i) \( (M, \varphi) \) contains \( C(0, 1) \) isometrically,
(ii) \( (M, \varphi) \) is isometrically universal for all separable metric spaces,
(iii) \( (M, \varphi) \) is isometrically universal for all separable reflexive Banach spaces.

It would be interesting to know whether the corresponding version of Theorems 7 and 8 holds for uniform embeddings. More precisely:

**Problem 1.** Let a separable complete metric space \( (M, \varphi) \) be uniformly universal for all separable reflexive Banach spaces (i.e., for each separable reflexive Banach space \( (R, \| \|) \) let there be an embedding \( f : R \to M \) such that both \( f \) and \( f^{-1} \) are uniformly continuous). Is \( (M, \varphi) \) uniformly universal for all separable metric spaces?

On the other hand, from the point of view of the Banach space theory it would be nice to know the answer to the following

**Problem 2.** Let a separable Banach space \( (X, \| \|) \) be Lipschitz universal for all separable reflexive Banach spaces. Does \( (X, \| \|) \) contain \( \varepsilon_0 \) isomorphically?

In view of Theorem 7, Problem 2 reduces to the question whether every separable Banach space \( (X, \| \|) \) Lipschitz containing \( \varepsilon_0 \) contains \( \varepsilon_0 \) isomorphically. It follows from Ribe’s theorem [8] (see also [5], Th. 5.1) that in such a case \( X \) contains isomorphically \( R_\alpha \)'s uniformly. On the other hand, it is known, [6], Th. 3.5, that if a conjugate Banach space \( (X^*, \| \|) \) Lipschitz contains \( \varepsilon_0 \) then \( X^* \) contains \( \varepsilon_0 \) isomorphically and therefore, by [2], it contains \( R_\alpha \).

Recursion theoretic operators and morphisms on numbered sets*

by

Henk Barendregt (Utrecht) and Giuseppe Longo** (Pisa)

Dedicated to Boffe Lys Nelson on her twelfth birthday

Abstract. An operator is a map \( \Phi : \mathcal{P} \to \mathcal{P} \). By embedding \( \mathcal{P} \) in two natural ways into the \( \lambda \)-calculus model \( \mathcal{P} \) and \( \mathcal{T} \), the computable maps on this latter structure induce classes of recursion operators.

§ 0. Introduction. With the notion of (pre complete) numbered set Ershov [3] gave a general framework for certain results in classical recursion theory. In his theory the notion of morphism is central. In [6] there is a definition of enumeration operators and (implicitly) of Turing operators. Although enumeration operators (restricted to the r.e. sets as numbered set) are morphisms, Turing operators are not even partial morphisms.

There is a natural correspondence between these (and other) classes of recursion theoretic operators and morphisms on an appropriate numbered set, via the constructive part of the \( \lambda \)-calculus models \( \mathcal{P} \) and \( \mathcal{T} \). The different classes of operators on \( \mathcal{P} \) are effective continuous maps obtained by embedding \( \mathcal{P} \) into \( \mathcal{P} \) or \( \mathcal{T} \) in two natural ways, giving \( \mathcal{P} \) either the Cantor or the Scott topology.

In particular Turing operators work on \( \mathcal{P} \) with the Cantor topology. This is implicit in Nerode's theorem, see [6], p. 154, relating \( \tau \)-reducibility to total Turing operators. Also a different proof will be given of a theorem in [6], p. 151, relating enumeration and Turing reducibility. Finally an interpolation result, in the sense of algebra, will be proved for total Turing operators.
