On cyclic groups

by

F. Szász (Debrecen)

To the memory of my dearly beloved, prematurely dead Master: professor T. Szél.

We treat in this paper the following group-theoretical problem for a certain characterization of cyclic groups among all groups. Let \( G \) be an arbitrary (and thus not necessarily abelian) group. The \( k \)th power of the group \( G \) is a subgroup \( G^k \) generated by the set of the \( k \)th powers of all group-elements. An arbitrary group \( G \) is called a group with property \( P \) if there exists to every subgroup \( H \) a rational integer \( k \) for which \( H = G^k \) holds. E. g. any cyclic group has the property \( P \).

We shall prove in this paper that the property \( P \) postulated for groups and the cyclic behaviour of the groups are equivalent, namely that a group with property \( P \) is always cyclic.

As we do not assume the group-operation to be commutative we write it multiplicatively. We call the neutral element of the group the unity and denote it by \( 1 \). A group is called torsion free if it has no element of finite order other than the unity. Moreover a group is called a torsion group if every element of the group has finite order. A torsion group is a \( p \)-group if the orders of group-elements are powers of a fixed prime number \( p \). A torsion group is called an elementary group if the order of any group-element is a square free number. We refer here to the ground theorem of finite abelian groups, according to which every abelian group with finitely many elements is the direct product of cyclic groups.

Every subgroup of an abelian group is evidently a normal subgroup of the group. A non-commutative group is termed hamiltonian if every subgroup is a normal subgroup of the group. E. g. the quaternion group \( Q \) generated by the elements \( a \) and \( b \) for which the relations \( a^2 = b^2 = 1 \) and \( ab = ba \) hold is a hamiltonian group. The fundamental theorem of R. Baer supplies an explicit description of all hamiltonian groups: every hamiltonian group is the direct product of the quaternion group and of an abelian group whose \( 2 \)-component (i. e. the set of all group-elements of 2-power order) is an elementary \( p \)-group. It is obvious that the factor group \( G/Z \) of a hamiltonian group \( G \) by the centre \( Z \) of the group \( G \) is always commutative \([1]\).

We now prove the following theorem:

\[ \text{Theorem.} \quad \text{An arbitrary group} \ G \ \text{is cyclic if and only if the group} \ G \ \text{has the property} \ P. \]

First of all we prove some Lemmas.

\[ \text{Lemma 1. Every homomorphic image} \ G' \ \text{of a group} \ G \ \text{with property} \ P \ \text{has likewise the property} \ P. \]

\[ \text{Proof.} \quad \text{Let} \ G \ \text{be an arbitrary group with property} \ P. \ \text{If} \ \varphi \ \text{is a homomorphic mapping of} \ G \ \text{onto the group} \ G', \ \text{then there exists in the group} \ G \ \text{a uniquely defined complete inverse image} \ H = \varphi^{-1}(H') \ \text{of an arbitrary subgroup} \ H' \ \text{of the group} \ G'. \ \text{There exists a rational integer} \ k \ \text{for which} \ H = G^k \ \text{holds. Let} \ h \in H \ \text{and} \ h' \in H' \ \text{be given so that} \ \varphi(h) = h'. \ \text{Then we can write that} \ h = g_1 \cdots g_k \in H = G^k \ \text{where} \ g_1, \ldots, g_k \ \text{are suitable elements of} \ G. \ \text{For this reason evidently} \ h' \in (G')^k, \ \text{therefore} \ \varphi((G')^k) \ \text{holds. On the other hand, if} \ g \in G, \ \text{then} \ g^k \in H, \ \text{therefore by} \ \varphi((G')^k) \ \text{obviously} \ H' = ((G')^k) \ \text{is true.} \]

\[ \text{Lemma 2. A group with property} \ P \ \text{is finite or torsion free.} \]

\[ \text{Proof.} \quad \text{If} \ g \in G \ \text{is an element of finite order and} \ O(g) = \nu > 1, \ \text{then with a suitable rational integer} \ k \ \text{the connection} \ \varphi(g^k) = G^k \ \text{holds. Therefore the order of any group-element is no greater than} \ k \ \nu, \ \text{namely} \ G \ \text{is at most} \ k \ \nu \text{-bounded. In this case} \ G \ \text{has only finitely many different subgroups, namely} \ G \ \text{is itself finite.} \]

\[ \text{Lemma 3. If an abelian group has the property} \ P, \ \text{then it is cyclic.} \]

\[ \text{Proof.} \quad \text{Let} \ G \ \text{be an abelian torsion free group with property} \ P. \ \text{Then there exists to the element} \ 1 \neq g \in G \ \text{a rational integer} \ n \neq 0 \ \text{for which} \ (g)^n = G^k \ \text{holds. Then the mapping} \ x \to x^n \ \text{is evidently an isomorphism of} \ G \ \text{into itself, therefore the group} \ G \ \text{is in this case cyclic.} \]

Now let \( G \) be a finite abelian group with property \( P \), which is by the above-mentioned ground theorem the direct product of cyclic groups. It is evidently sufficient to prove our Lemma for \( p \)-groups, because every \( p \)-component, as a direct factor, has by Lemma 1 likewise the property \( P \), and therefore from this proof of our Lemma already follows the cyclic behaviour of \( G \) itself. There exists a direct factor \( A_1 = 1 \) of the \( p \)-component group \( G_1 \) of the group \( G \) for which with a suitable subgroup \( H_0 \) obviously \( G_1 = A_1 \times H_0 \) holds. Then \( A_1 = G_1 \), and we can assume that \( s = p^m \) \((m \geq 0)\). In this case \( A_1 = A_1^s \times H_0^s \), and thus \( A_1 = A_1^s \), namely \( s = 1 \). Therefore the subgroup \( G_1 \) and the group \( G \) are cyclic.
The proof of the theorem. Let \( G \) be an arbitrary group with property \( P \). Then every subgroup of the group \( G \) is by the definition of the \( k \)th power of the group \( G \) a normal subgroup of \( G \). Let \( Z \) be the centre of \( G \), then the factor group \( G/Z \) is by the above-mentioned ground theorem of R. Baer on the hamiltonian groups, necessarily abelian, and by Lemma 1 has the property \( P \). Therefore \( G/Z \) is by Lemma 3 cyclic, which is evidently equivalent to the commutativity of the group \( G \). But then \( G \) is by Lemma 3 likewise cyclic.

On the other hand every cyclic group has the property \( P \), and therefore the proof is complete.

On antipodal sets on the sphere and on continuous involutions *

by

J. W. Jaworowski (Warszawa)

1. Preliminaries

1. The sphere \( S_n \). Let \( S_n \) be the \( n \)-sphere in the \((n+1)\)-dimensional Euclidean space \( E_{n+1} \), i.e., the set of points \( x \in E_{n+1} \) with \( |x|=1 \). We denote by \( a \) the antipodal mapping of \( S_n \); it is defined by \( a(x) = -x \), for every \( x \in S_n \). The set \( \Delta \subset S_n \) is called antipodal if \( a(A) = A \).

2. True chains. Let \( M \) be a metric space and \( \varepsilon > 0 \). By an \( \varepsilon \)-simplex of \( M \) we understand a finite subset of \( M \) with diameter \(< \varepsilon \). In a known manner we introduce the notions of \( \varepsilon \)-chains and \( \varepsilon \)-cycles modulo 2 of \( M \). Since in the sequel we shall use the homology theory modulo 2 only (with the exception of Chapter IV), the words "modulo 2" will be omitted. The boundary of a chain \( \varepsilon \) we denote by \( \varepsilon \partial \). By the boundary of a 0-dimensional simplex we understand the number 1 considered as a rest modulo 2. The rest 0 and 1 modulo 2 may be considered as \((-1)\)-dimensional cycles. A \( p \)-dimensional \( \varepsilon \)-cycle \( \partial \varepsilon \) is said to be \( \eta \)-homologous to zero in \( M \) if there exists in \( M \) a \((p-1)\)-dimensional \( \eta \)-chain \( \partial \varepsilon' \) such that \( \partial \varepsilon' = \gamma \partial \).

A sequence of chains \( \varepsilon = (\varepsilon_i) \) is called a \( p \)-dimensional true chain of \( M \) if there exists a compact subset \( C \) of \( M \) and a sequence \( (a_i) \) of positive numbers convergent to zero and such that \( \varepsilon_i \) is a \( p \)-dimensional \( \varepsilon \)-chain of \( C \). A true chain \( \varepsilon = (\varepsilon_i) \) is called a true cycle if \( 2\varepsilon = (2\varepsilon_i) = 0 \). Let \( \varepsilon = (\varepsilon_i) \) be a \( p \)-dimensional true cycle of \( M \). Then \( \varepsilon \) is said to be homologous to zero in \( M \) if, for every \( \varepsilon > 0 \), there exists an \( i \) such that \( \gamma_i \) is \( \varepsilon \)-homologous to zero in \( M \), for \( i > i \); it is called convergent in \( M \) if the true cycle \( (\varepsilon_i + \gamma_i) \) is homologous to zero in \( M \); if there exists a number \( \eta > 0 \) such that no cycle \( \gamma_i \) is \( \eta \)-homologous to zero in \( M \), then the true cycle \( \varepsilon \) is called totally nonhomologous to zero in \( M \).

We shall denote by \( H_p(M) \) the \( p \)-dimensional homology group (modulo 2) of \( M \) based on the convergent cycles.

* The main results of this paper were published without proof in [7] and [8].
