

where  $\tilde{\kappa}(j) = \kappa(i(j))$  and  $\tilde{a}_j = a_{i(j)}$ . Since the spaces  $D(\kappa, a)$  and  $D(\tilde{\kappa}, \tilde{a})$  are isomorphic it follows by Theorem 1 that they are quasi-diagonally isomorphic. This proves the theorem.

### A non-regular Toeplitz flow with preset pure point spectrum

by

T. DOWNAROWICZ (Wrocław) and Y. LACROIX (Brest)

**Abstract.** Given an arbitrary countable subgroup  $\sigma_0$  of the torus, containing infinitely many rationals, we construct a strictly ergodic 0-1 Toeplitz flow with pure point spectrum equal to  $\sigma_0$ . For a large class of Toeplitz flows certain eigenvalues are induced by eigenvalues of the flow  $Y$  which can be seen along the aperiodic parts.

**Introduction.** In this paper we continue the study of Toeplitz flows initiated in 1984 by S. Williams in her work [W]. Toeplitz sequences have been known earlier (e.g. [O], [G-H], [J-K]), but it is the construction of Williams that is exploited in most of later works on Toeplitz sequences (e.g. [B-K1], [D], [B-K2], [I-L], [D-K-L], [I]). Spectral properties of Toeplitz flows have been studied in [I-L] and [I]. In this note we develop the method introduced by A. Iwanik in [I]. Each eigenvalue  $\gamma$  obtained there satisfies a certain equation formulated in Section I of this paper as (3). In [I], however, this equation remains unsolved, and an irrational  $\gamma$  is obtained by constructing uncountably many Toeplitz flows with different eigenvalues.

We have succeeded in solving the equation (3) simultaneously for an arbitrary countable set of  $\gamma$ 's. This enables us to prove the existence of strictly ergodic Toeplitz flows with an arbitrarily preset pure point spectrum containing infinitely many rationals.

Section I contains slightly modified formulations of the results of [I]. We rid the constructions of technical details used in [I] to produce uncountably many sequences. For a large class of Toeplitz flows we identify certain eigenvalues not arising from the maximal uniformly continuous factor. We also adapt the cohomology statement of [I] to the countable product of tori.

1991 *Mathematics Subject Classification*: Primary 28D05, 54H20.

*Key words and phrases*: Toeplitz sequence, pure point spectrum, strict ergodicity, group extension.

Research of the second author supported by C.A.F. Nord Finistère.

Section II is devoted to presenting how equation (3) can be solved for an arbitrary countable set of  $\gamma$ 's.

In Section III we put the previous theorems together to obtain the desired Toeplitz flow with the preset spectrum. Attention is paid to strict ergodicity.

**Preliminaries.** Let  $(X, \mu, T)$  be a standard probability measure preserving dynamical system. The *point spectrum*  $\sigma_0(T)$  is the set of all eigenvalues of the induced unitary operator  $U_T$  on  $L^2(\mu)$ . We say that the dynamical system has *pure point spectrum* if  $\sigma_0(T)$  supports the entire spectral measure of  $U_T$ . If in addition  $\mu$  is ergodic, then  $\sigma_0(T)$  is a countable subgroup of the torus and  $(X, \mu, T)$  is measure-theoretically isomorphic to  $(G, \lambda, g)$ , where  $G$  is the dual compact monothetic group to  $\sigma_0(T)$  with Haar measure  $\lambda$  and rotation by a generator  $g$ .

A *Toeplitz sequence* is a non-periodic element  $\eta \in \Sigma^{\mathbb{Z}}$  ( $\Sigma$  a finite set) such that

$$(\forall n \in \mathbb{Z})(\exists p \in \mathbb{N})(\forall m \in \mathbb{Z}) \quad \eta(mp + n) = \eta(n)$$

(see [W] for a general reference on Toeplitz sequences). For each Toeplitz sequence there exists a sequence of periods  $(p_j)_{j \in \mathbb{N}}$  with  $p_j \mid p_{j+1}$  for each  $j$ , defining a partition of  $\mathbb{Z}$  into  $p_j$ -periodic sets  $Z_j$  along which  $\eta$  is  $p_j$ -periodic but not periodic with any smaller period. Every such sequence  $(p_j)$  is called a *period structure* for  $\eta$ . Each subsequence of  $(p_j)$  is again a period structure for  $\eta$ . A Toeplitz sequence is called *regular* if the sum  $d$  of the densities in  $\mathbb{Z}$  of  $Z_j$  equals 1.

It is known that the orbit closure  $\overline{O}(\eta)$  of a Toeplitz sequence  $\eta$  is minimal for the shift transformation  $S$ . Now, if  $\eta$  is regular, then  $(\overline{O}(\eta), S)$  is *strictly ergodic*, i.e., in addition to minimality it carries a unique invariant (probability) measure. In this case, almost all elements of  $\overline{O}(\eta)$  are also Toeplitz sequences. In the non-regular case each of the (possibly many) invariant measures is carried by the set  $W(\eta)$  of (non- Toeplitz) elements with doubly infinite aperiodic part. We define

$$Y(\eta) = \overline{\{y(\omega) : \omega \in W(\eta)\}},$$

where  $y(\omega)$  is the sequence to be read along the aperiodic part of  $\omega$  (position zero of  $y(\omega)$  is defined by the smallest positive position in the aperiodic part of  $\omega$ ). Of course,  $Y(\eta) \subset \Sigma^{\mathbb{Z}}$  is shift-invariant. Since  $W(\eta)$  is not closed, in the general case we have no guarantee that  $\{y(\omega) : \omega \in W(\eta)\}$  is itself a closed set. However, in the further constructions of this paper this is the case, so the closure in the above definition can as well be omitted.

The maximal uniformly continuous factor of  $(\overline{O}(\eta), S)$  is known to be topologically isomorphic to the unit-rotation on the group of  $p$ -adic integers, where  $p$  stands for  $(p_j)$ , a period structure of  $\eta$ . If  $G_p$  is viewed as a

compactification of  $\mathbb{Z}$ , then by  $C_j$  we denote the closure of  $Z_j$ . The sets  $C_j$  are disjoint and each of them is a union of some number  $l_j$  of cosets of the form  $H_j + k$ , where  $H_j = p_j G_p$ ,  $0 \leq k < p_j$ . We define

$$(1) \quad C = \bigcup_{j \geq 1} C_j.$$

Note that

$$d = \sum_{j \geq 1} \frac{l_j}{p_j} = \mu_p(C),$$

where  $\mu_p$  is the Haar measure on  $G_p$ . (Practically, we construct Toeplitz sequences by induction, filling in step  $j$  some  $l_j$  yet unfilled positions of the interval  $[0, p_j)$ , and repeating the pattern with the period  $p_j$ .)

There is a natural Borel measurable mapping  $\psi$  from  $W(\eta)$  into the product  $G_p \times Y(\eta)$  sending  $\omega$  to  $(h, y)$ , where  $h$  is the image of  $\omega$  by the maximal uniformly continuous factor, and  $y = y(\omega)$ . The shift  $S$  then corresponds to a piecewise power skew product transformation

$$S_C(h, y) = (h + 1, S^{h \notin C} y),$$

where " $h \notin C$ " denotes the logical 0-1-value,  $S^1 = S$  and  $S^0 = \text{Id}$  (the identity map). If  $\eta$  is a Toeplitz sequence "constructed from a subshift  $Y$ ", then  $Y(\eta) = Y$ , and for each invariant measure  $\nu$  on  $Y$ , there exists an invariant measure  $\lambda$  on  $(\overline{O}(\eta), S)$  such that  $\psi$  becomes a measure-theoretic isomorphism between  $(\overline{O}(\eta), \lambda, S)$  and  $(G_p \times Y, \mu_p \times \nu, S_C)$  (see [W, Theorem 4.5]). In the strictly ergodic case we need not refer to [W]. Sufficient is the following easy observation:

**LEMMA 1.** *If the piecewise power skew product  $(G_p \times Y(\eta), S_C)$  is strictly ergodic then  $(\overline{O}(\eta), S)$  is strictly ergodic and  $\psi$  is a measure-theoretic isomorphism between these flows.*

**Proof.** The set  $W(\eta)$  carrying all invariant measures of  $(\overline{O}(\eta), S)$  is mapped by  $\psi$  in a 1-1 way onto an invariant subset of  $G_p \times Y(\eta)$ . By strict ergodicity, this must be a full measure subset for the unique invariant measure. Thus  $W(\eta)$  also carries a unique invariant measure. ■

Inspired by [I], we will assume that for each  $j \in \mathbb{N}$ ,

$$\text{either } C_j \subset H_j \cup (H_j + 1) \cup \dots \cup (H_j + r_j - 1) \\ \text{or } C_j \subset (H_j - r_j) \cup (H_j - r_j + 1) \cup \dots \cup (H_j - 1)$$

for a sequence  $(r_j)$  such that

$$(2) \quad \sum_{j \geq 1} \frac{r_j}{p_j} < \infty.$$

As is not difficult to see, (2) already implies non-regularity of  $\eta$ . Nevertheless, we need the flow  $(\bar{O}(\eta), S)$  to be strictly ergodic, in order to insure that the measure-theoretic notions do not depend on the choice of the invariant measure (except for Theorem 1, which holds separately for each invariant measure  $\nu$  on  $Y(\eta)$ ).

**I. Iwanik's equation.** We will view the torus  $\mathbb{T}$  additively, as parameterized by the interval  $[-1/2, 1/2)$ . It has to be noted that in this setting the expression  $\frac{nx}{m}$  for  $x \in \mathbb{T}$  ( $m > n$ , some positive integers) does not have a definite meaning, so we shall use

$$\frac{(nx)_{\mathbb{T}}}{m}$$

to indicate that dividing by  $m$  is applied to the element of  $\mathbb{T}$  arising from  $nx$ . Observe that then the above function of  $x$  is linear on each interval along which  $(nx)_{\mathbb{T}} \in (-1/2, 1/2)$ . In other expressions we can safely skip the indicator " $(\ )_{\mathbb{T}}$ ". The absolute value function is also applied to the element of  $\mathbb{T}$  in the above parameterization. In other words,  $|nx|$  denotes the distance of the real number  $nx$  from the nearest integer. In our constructions elements of the torus (viewed as eigenvalues) belonging to the following set (for a given Toeplitz sequence) will play the crucial role:

$$A = \left\{ x \in \mathbb{T} : \sum_{j \geq 1} |l_j x| < \infty \right\},$$

where  $(l_j)$  is as described earlier for Toeplitz sequences. It is worth noticing (and not hard to see) that the set  $A$  always has Lebesgue measure zero. It can be countable (e.g. for  $(l_j)$  a geometric sequence), but if  $l_j$  increases sufficiently quickly then  $A$  contains a Cantor set.

Note that now a  $\mathbb{T}$ -valued function  $f$  is an eigenfunction pertaining to an eigenvalue  $\alpha \in \mathbb{T}$  if  $f(S\omega) = f(\omega) + \alpha$ .

**THEOREM 1.** *Let  $(\bar{O}(\eta), \lambda, S)$  be a Toeplitz flow measure-theoretically isomorphic via the map  $\psi$  to the skew product  $(G_p \times Y(\eta), \mu_p \times \nu, S_C)$  for some invariant measure  $\nu$  on  $Y(\eta)$ . Assume also (2). Let  $\alpha \in A$  be an eigenvalue for  $(Y(\eta), \nu, S)$  corresponding to an eigenfunction  $f : Y(\eta) \rightarrow \mathbb{T}$ . Then*

$$(3) \quad \gamma(\alpha) = \alpha - \sum_{j \geq 1} \frac{(l_j \alpha)_{\mathbb{T}}}{p_j}$$

is an eigenvalue for  $(\bar{O}(\eta), \lambda, S)$ . The corresponding eigenfunction has the form  $\tilde{f}(\omega) = g(h) + f(y)$ , where  $(h, y) = \psi(\omega)$  and  $g : G_p \rightarrow \mathbb{T}$ .

**Proof.** We need to construct the function  $g : G_p \rightarrow \mathbb{T}$ . Fix  $j \in \mathbb{N}$ . Recall that  $C_j$  is a union of  $l_j$  cosets  $H_j + k$ . Now, for  $h \in H_j$  we define

$$(4) \quad g_j(h) = 0$$

and

$$(5) \quad g_j(h+k+1) = \begin{cases} g_j(h+k) - \frac{(l_j \alpha)_{\mathbb{T}}}{p_j} & \text{if } h+k \notin C_j, \\ g_j(h+k) - \frac{(l_j \alpha)_{\mathbb{T}}}{p_j} + \alpha & \text{if } h+k \in C_j, \end{cases}$$

for  $k = 0, 1, \dots, p_j - 1$ . Observe that the formula (5) applied to  $k = p_j - 1$  yields

$$g_j(h+p_j) = g_j(h) - p_j \frac{(l_j \alpha)_{\mathbb{T}}}{p_j} + l_j \alpha = 0,$$

which agrees with (4), since  $H_j + p_j = H_j$ . Also note that  $h+k \notin C_j$  for  $p_j - r_j$  consecutive values of  $k$  either ending with  $p_j - 1$  or starting with 0, and hence  $g_j$  differs from zero at the corresponding cosets by at most

$$\left| (p_j - r_j) \frac{(l_j \alpha)_{\mathbb{T}}}{p_j} \right| \leq |l_j \alpha|,$$

which is summable over  $j$  since  $\alpha \in A$ . The remaining part of  $G_p$  has measure  $r_j/p_j$ , also assumed in (2) to be a summable sequence. It is now obvious that the function

$$g(h) = \sum_{j \geq 1} g_j(h)$$

is well defined as a convergent series on a set of measure 1 in  $G_p$ . On the same set, by (5),

$$(6) \quad g(h+1) = \begin{cases} g(h) - \sum_{j \geq 1} \frac{(l_j \alpha)_{\mathbb{T}}}{p_j} & \text{if } h \notin C, \\ g(h) - \sum_{j \geq 1} \frac{(l_j \alpha)_{\mathbb{T}}}{p_j} + \alpha & \text{if } h \in C, \end{cases}$$

because in the second case  $h \in C_j$  for exactly one  $j$ .

Finally, as announced, we define  $\tilde{f}(\omega) = g(h) + f(y)$  and we check

$$\begin{aligned} \tilde{f}(S\omega) &= g(h+1) + f(S^h y) \\ &= \begin{cases} g(h) - \sum_{j \geq 1} \frac{(l_j \alpha)_{\mathbb{T}}}{p_j} + f(Sy) & \text{if } h \notin C, \\ g(h) - \sum_{j \geq 1} \frac{(l_j \alpha)_{\mathbb{T}}}{p_j} + \alpha + f(y) & \text{if } h \in C, \end{cases} \end{aligned}$$

$$= \tilde{f}(\omega) + \alpha - \sum_{j \geq 1} \frac{(l_j \alpha)_{\mathbb{T}}}{p_j},$$

almost everywhere for the product measure, as desired. ■

Note that if  $\alpha$  is rational then  $\alpha \in A$  implies  $(l_j \alpha)_{\mathbb{T}} = 0$  starting from some  $j_0$ . Thus  $\gamma(\alpha)$  is also rational.

The equation (3) along with the function  $g$  of Theorem 1 can also be used to produce measure-theoretic isomorphisms between group extensions over  $G_p$  by  $\mathbb{T}^\infty$ , where  $\mathbb{T}^\infty$  denotes the product of countably many tori. This will be used later for further investigations of Toeplitz flows.

We fix the sequence  $(p_j)$  (and hence the group  $G_p$ ) and an open set  $C \subset G_p$  represented by the formula (1) and satisfying (2). The sequence  $(l_j)$  and the set  $A$  are therefore also determined. We do not need to further specify the Toeplitz sequence  $\eta$ .

**THEOREM 2.** *Let  $\alpha = (\alpha_i)_{i \in \mathbb{N}}$  with  $\alpha_i \in A$  for each  $i$ . Let  $\gamma_i = \gamma(\alpha_i)$ , and let  $\gamma = (\gamma_i)_{i \in \mathbb{N}}$ . If  $1, \gamma_1, \gamma_2, \dots$  are rationally independent then the group extension  $(G_p \times \mathbb{T}^\infty, T_C)$ , where*

$$T_C(h, \mathbf{x}) = (h + 1, \mathbf{x} + \alpha^{h \notin C}),$$

*is strictly ergodic and measure-theoretically isomorphic to the rotation of  $G_p \times \mathbb{T}^\infty$  by the generator  $1 \times \gamma$ .*

*Proof.* As in [I], we show that the cocycle  $\alpha^{h \notin C}$  is cohomologous to the constant cocycle  $\gamma$ . To this end we check that the cohomology function  $\mathbf{g} : G_p \rightarrow \mathbb{T}^\infty$  is given by

$$\mathbf{g}(h) = (g_i(h))_{i \in \mathbb{N}},$$

where  $g_i$  now denotes the function  $g$  constructed as in the proof of Theorem 1 for  $\alpha_i$  and  $\gamma_i$ . In fact, by the property (6) of each  $g_i$ , we have

$$(\alpha^{h \notin C} + \mathbf{g}(h + 1) - \mathbf{g}(h))_i = \begin{cases} \alpha_i - \sum_{j \geq 1} \frac{(l_j \alpha_i)_{\mathbb{T}}}{p_j} & \text{if } h \notin C, \\ -\sum_{j \geq 1} \frac{(l_j \alpha_i)_{\mathbb{T}}}{p_j} + \alpha_i & \text{if } h \in C, \end{cases} = \gamma_i,$$

$\mu_p$ -almost everywhere, which is the cohomology equation.

Since the rotation on  $G_p \times \mathbb{T}^\infty$  is ergodic, so is the group extension  $T_C$ , hence, by a theorem of Furstenberg [F], the latter is also strictly ergodic. ■

The group extension  $(G_p \times \mathbb{T}^\infty, T_C)$  carries at least as many invariant measures as  $(\mathbb{T}^\infty, \alpha)$  (corresponding product measures are  $T_C$ -invariant), hence we immediately deduce

**COROLLARY 1.** *With the assumptions of Theorem 2, the numbers  $1, \alpha_1, \alpha_2, \dots$  are rationally independent. ■*

(The above fact can also be deduced for  $\alpha_i$ 's belonging to  $A$  directly from (3). The assumption (2) is not essential.)

**Remark 1.** With a slight modification of the set  $C$ , Theorem 2 also holds if we add one (finitely many reduces to one) rational number  $\alpha_0 = 1/n$ , where  $n$  is relatively prime to all the  $p_j$ 's. The group  $\mathbb{T}^\infty$  is then replaced by  $\mathbb{Z}_n \times \mathbb{T}^\infty$  ( $\mathbb{Z}_n$  is viewed as a subgroup of  $\mathbb{T}$ ). Next, all  $l_j$ 's must be chosen multiples of  $n$ , hence we obtain  $\gamma_0 = \alpha_0$ . The cohomology function on the added axis is then  $g_0 = 0$ . The ergodicity and strict ergodicity are maintained.

**II. Solving Iwanik's equation.** Let the group  $G_p$  be given. By  $p$ -rationals we will mean the elements of the spectrum of the group rotation  $(G_p, 1)$ . For technical reasons we need to introduce a notation for the number of "unfilled positions". And so, for given sequences  $(p_j)$  and  $(l_j)$  we define

$$m_j = p_j \left( 1 - \sum_{k \leq j} \frac{l_k}{p_k} \right).$$

Let  $(\delta_j)$  be a summable sequence with  $0 < \delta_j < 1/2$  for each  $j$ .

**THEOREM 3.** *For every sequence  $(\gamma_i)$  of elements of  $\mathbb{T}$  there exist*

(a) *increasing sequences  $(l_j)$  and  $(p_j)$  with  $(p_j)$  defining  $G_p$ , and such that for each  $j \in \mathbb{N}$ ,*

$$(7_j) \quad l_j \text{ is a multiple of } m_{j-1} \quad \text{and} \quad l_j < \frac{\delta_j p_j}{p_{j-1}},$$

(b) *a sequence  $(\beta_i)$  of  $p$ -rationals, and*

(c) *a sequence  $(\alpha_i)$  such that  $\alpha_i \in A$  and  $\gamma(\alpha_i) = \gamma_i + \beta_i$  for each  $i \in \mathbb{N}$ .*

*Proof.* Fix a sequence  $(\varepsilon_j)$  of positive numbers such that

$$(8) \quad \varepsilon_1 < \frac{1}{6} \quad \text{and} \quad \sum_{j > k} \varepsilon_j < \varepsilon_k \quad (k \geq 1).$$

We shall inductively find the numbers  $l_j$  and  $p_j$  satisfying (7<sub>j</sub>), define  $\beta_j$ , and construct a triangular array  $(\alpha_{i,j})_{j \in \mathbb{N}, 1 \leq i \leq j+1}$  such that for every pair  $i, j$  with  $i \leq j$ ,

$$(9_j) \quad \alpha_{i,j} - \sum_{k \leq j} \frac{(l_k \alpha_{i,j})_{\mathbb{T}}}{p_k} = \gamma_i + \beta_i,$$

and

$$(10_j) \quad |l_k \alpha_{i,j}| < 2\varepsilon_k + \varepsilon_{k+1} + \dots + \varepsilon_j \quad \text{for all } 1 \leq k \leq j.$$

Step 1. Let  $\beta_1 = 0$  and find  $l_1 \geq 1$  such that

$$|l_1 \gamma_1| < \varepsilon_1$$

(this is possible for both rational and irrational  $\gamma_1$ ). Then let  $p_1$  be an element of the sequence defining  $G_p$  such that  $l_1 < \delta_1 p_1$ , as in (7<sub>1</sub>) (set  $p_0 = m_0 = 1$ ). Observe that for  $x \in [\gamma_1 - \varepsilon_1/l_1, \gamma_1 + \varepsilon_1/l_1]$  we have  $(l_1 x)_\mathbb{T} \in (-2\varepsilon_1, 2\varepsilon_1) \subset (-1/2, 1/2)$ , so that the function

$$x - \frac{(l_1 x)_\mathbb{T}}{p_1}$$

increases linearly (with slope  $1 - l_1/p_1$ ) from a value  $< \gamma_1$  to a value  $> \gamma_1$  (seen by an elementary calculation). Thus, there exists an  $\alpha_{1,1} \in [\gamma_1 - \varepsilon_1/l_1, \gamma_1 + \varepsilon_1/l_1]$  with

$$(9_1) \quad \alpha_{1,1} - \frac{(l_1 \alpha_{1,1})_\mathbb{T}}{p_1} = \gamma_1.$$

Of course, we have

$$(10_1) \quad |l_1 \alpha_{1,1}| < 2\varepsilon_1.$$

Step  $j+1$ . Throughout description of this step,  $j \geq 1$  has a fixed value, while  $i$  and  $k$  range between 1 and  $j$  (later we also admit  $i = j+1$  and  $k = j+1$ ). Suppose we have already defined all the numbers  $\beta_i$ ,  $l_k$ ,  $p_k$  and  $\alpha_{i,j}$ , so that the requirements on  $l_k$  and  $p_k$  of (7<sub>k</sub>) as well as the conditions (9<sub>j</sub>) and (10<sub>j</sub>) are satisfied. First notice that

$$(11) \quad |l_k x| < 2\varepsilon_k + \varepsilon_{k+1} + \dots + \varepsilon_j$$

holds for each  $k$  if  $x$  is in some open interval  $U_j$  around 0. In particular, by (8),  $(l_k x)_\mathbb{T} \in (-1/2, 1/2)$  and thus the function

$$x - \sum_{k \leq j} \frac{(l_k x)_\mathbb{T}}{p_k}$$

increases linearly (with positive slope  $1 - \sum_{k \leq j} l_k/p_k$ ) on  $U_j$ . So, it is possible to find  $x_0 \in U_j$  and a  $p$ -rational  $\beta_{j+1}$  with

$$(12) \quad x_0 - \sum_{k \leq j} \frac{(l_k x_0)_\mathbb{T}}{p_k} = \gamma_{j+1} + \beta_{j+1}.$$

We let  $\alpha_{j+1,j} = x_0$ , and so, by (11) and (12), the conditions (9<sub>j</sub>) and (10<sub>j</sub>) are additionally satisfied with  $i = j+1$ .

Now, we repeat the procedure of step 1. Find  $l_{j+1} > l_j$ , a multiple of  $m_j$ , such that

$$(13) \quad |l_{j+1} \alpha_{i,j}| < \varepsilon_{j+1} \quad \text{for all } 1 \leq i \leq j+1$$

(this is possible regardless of the rational independence of the  $\alpha_{i,j}$ 's), and then pick  $p_{j+1}$  from the sequence defining  $G_p$  such that  $l_{j+1} < \delta_{j+1} p_{j+1}/p_j$ , as required in (7<sub>j+1</sub>).

In the sequel  $i$  denotes a fixed integer between 1 and  $j+1$ . For

$$x \in [\alpha_{i,j} - \varepsilon_{j+1}/l_{j+1}, \alpha_{i,j} + \varepsilon_{j+1}/l_{j+1}]$$

we have, by (10<sub>j</sub>),

$$(14) \quad |l_k x| < 2\varepsilon_k + \varepsilon_{k+1} + \dots + \varepsilon_j + \varepsilon_{j+1} \quad \text{for all } 1 \leq k \leq j.$$

Next, by (13), we also have  $|l_{j+1} x| < 2\varepsilon_{j+1}$  on the same interval, which extends (14) to  $k = j+1$ . As before, by (8), the function

$$x - \sum_{k \leq j+1} \frac{(l_k x)_\mathbb{T}}{p_k}$$

increases linearly (with positive slope  $1 - \sum_{k \leq j+1} l_k/p_k$ ) on the above interval, assuming at the endpoints values on opposite sides of  $\gamma_i + \beta_i$  (easily calculated using (9<sub>j</sub>)). Hence, there exists in this interval an  $\alpha_{i,j+1}$  satisfying

$$(9_{j+1}) \quad \alpha_{i,j+1} - \sum_{k \leq j+1} \frac{(l_k \alpha_{i,j+1})_\mathbb{T}}{p_k} = \gamma_i + \beta_i.$$

Of course, by (14), we also have

$$(10_{j+1}) \quad |l_k \alpha_{i,j+1}| < 2\varepsilon_k + \varepsilon_{k+1} + \dots + \varepsilon_{j+1} \quad \text{for all } 1 \leq k \leq j+1.$$

This completes the induction.

It follows from the construction that for fixed  $i$  the sequence  $(\alpha_{i,j})_{j \geq i}$  is Cauchy, so  $\alpha_i = \lim_j \alpha_{i,j}$  exists. We easily notice that (10<sub>j</sub>) and (8) yield

$$|l_k \alpha_i| \leq \varepsilon_k + \sum_{j \geq k} \varepsilon_j < 3\varepsilon_k,$$

and so  $\alpha_i \in A$ . Further, by a standard argument with separately estimating a tail of a series and the corresponding finite sum, (9<sub>j</sub>) and (10<sub>j</sub>) imply that  $\gamma(\alpha_i) = \gamma_i + \beta_i$ , as desired. ■

**III. Strictly ergodic Toeplitz flow.** First, we need to represent an ergodic rotation of the infinite-dimensional torus by a subshift. Then we state our main result.

LEMMA 2. *Let  $(\mathbb{T}^\infty, \alpha)$  be ergodic. Then there exists a minimal 0-1-subshift  $(Y, S)$  and a continuous factor map  $\phi : Y \rightarrow \mathbb{T}^\infty$  invertible except on a subset  $F \subset \mathbb{T}^\infty$  of Haar measure zero.*

Proof. Let  $0 = a_0 < a_1 < a_2 < \dots < 1/2$  be a sequence in  $\mathbb{T}$ . Next

define

$$J = \bigcup_{n \geq 1} [a_{n-1}, a_n] \times [a_{n-2}, a_{n-1}] \times \dots \times [a_0, a_1] \times \mathbb{T} \times \mathbb{T} \times \dots$$

It is easy to check that  $J$  and its complement constitute a topological generator for the flow  $(\mathbb{T}^\infty, \alpha)$ . The existence of a 0-1-subshift  $(Y, S)$  and of a continuous factor map  $\phi : Y \rightarrow \mathbb{T}^\infty$  invertible except on the subset

$$F = \bigcup_{n \in \mathbb{Z}} (\partial J + n\alpha)$$

follow from [D-G-S, Sec. 15] (where  $\partial J$  denotes the boundary of  $J$ ). Of course  $\partial J \subset [0, 1/2] \times [0, 1/2] \times [0, 1/2] \times \dots$  is of Haar measure zero. By minimality of  $\mathbb{T}^\infty$ ,  $Y$  can be chosen minimal. ■

**THEOREM 4.** *Let  $\sigma_0$  be a countable subgroup of  $\mathbb{T}$  containing infinitely many rationals. Then there exists a strictly ergodic Toeplitz flow  $(\bar{O}(\eta), S)$  with pure point spectrum  $\sigma_0$ .*

**PROOF.** Every such subgroup  $\sigma_0$  is generated by the union of two sets:  $\{1/p_j : j \in \mathbb{N}\}$  and  $\{\gamma_i : i \in I\}$ , where  $p_j | p_{j+1}$  for each  $j$ ,  $I$  is either empty or finite or countable, and (if  $I$  is non-empty) the  $\gamma_i$ 's are rationally independent. We proceed with the proof for  $I = \mathbb{N}$ , for the other cases see Remark 2 below.

Let  $G_p$  be the group of  $p$ -adic integers defined by the sequence  $(p_j)$ . We now apply Theorem 3 (with some fixed sequence  $(\delta_j)$ ) to obtain a subsequence of  $(p_j)$  (from now on  $(p_j)$  will denote this subsequence), and sequences  $(l_j)$ ,  $(\beta_i)$ ,  $(\alpha_i)$  with all the properties stated there. It is important that the set  $\{1/p_j : j \in \mathbb{N}\} \cup \{\gamma_i + \beta_i : i \in I\}$  still generates the same group  $\sigma_0$ . From now on  $\gamma_i$  will denote  $\gamma_i + \beta_i$ . These  $\gamma_i$ 's are also rationally independent.

Let  $(Y, S)$  be a subshift (we will specify it a little later, at this moment we are more interested in defining the set  $C$ ). We apply a simplified (compared to [W]) inductive construction of the Toeplitz sequence  $\eta$  from  $Y$ : in step  $j$  we fill the initial (for odd  $j$ ) or terminal (for even  $j$ )  $l_j$  yet unfilled positions in  $[0, p_j]$  using a block of length  $l_j$  appearing in  $Y$ , and repeat this pattern with period  $p_j$ . Of course, this induction also defines the set  $C \subset G_p$ . Observe that the last inequality of (7<sub>j</sub>) implies (2) (in our case  $r_j \leq l_j p_{j-1}$ ).

So, we can use Theorem 2, from which  $(G_p \times \mathbb{T}^\infty, 1 \times \gamma)$ , the monothetic group rotation with pure point spectrum  $\sigma_0$ , is measure-theoretically isomorphic to the strictly ergodic (with the product measure) group extension  $(G_p \times \mathbb{T}^\infty, T_C)$ , where  $T_C$  is defined by the cocycle  $\alpha^{h \notin C}$ , and  $\alpha$  is the sequence of  $\alpha_i$ 's. By Corollary 1, the element  $\alpha$  is a generator of  $\mathbb{T}^\infty$ .

We can now specify the subshift  $(Y, S)$  to be the representation of  $(\mathbb{T}^\infty, \alpha)$  of Lemma 2. The group extension  $(G_p \times \mathbb{T}^\infty, T_C)$  is a topological factor, via

$\text{Id} \times \phi$ , of the piecewise power skew product  $(G_p \times Y, S_C)$ , and this factor map is invertible except on the set  $G_p \times F$  of product measure zero. Now, any two invariant measures on the skew product are mapped to the product measure on the group extension (strict ergodicity), hence they may differ only on the preimage of  $G_p \times F$ . This set, however, is of any such measure zero, so the difference is inessential. Thus strict ergodicity of  $(G_p \times Y, S_C)$  is proved. Clearly, the map  $\text{Id} \times \phi$  provides also a measure-theoretic isomorphism.

Finally, since each  $l_j$  is a multiple of  $m_{j-1}$ , we have  $Y(\eta) \subset Y$  (see proof of the analogous inclusion in [W, Lemma 4.3]). By minimality of  $Y$  we have equality, and Lemma 1 says that  $(\bar{O}(\eta), S)$  is strictly ergodic and measure-theoretically isomorphic to  $(G_p \times Y, S_C)$ . ■

**Remark 2.** For  $I$  finite the same proof applies (Theorem 2 works as well for finite products of tori, in Theorem 3 put  $\gamma_i = 0$  for  $i > \#I$ ). Any regular Toeplitz sequence over  $G_p$  works for  $I = \emptyset$ .

**Remark 3.** By essentially the same proof, if  $n = p_1$  is relatively prime with  $q_j = p_j/p_1$  for each  $j \geq 2$ , then we can obtain  $\sigma_0$  for a Toeplitz sequence over  $G_q$ . We let  $\gamma_0 = 1/n$  and replace  $\mathbb{T}^\infty$  by  $\mathbb{Z}_n \times \mathbb{T}^\infty$ . Theorem 2 applies by Remark 1 with  $\alpha_0 = \gamma_0$  (cf. [I, Theorem 2], which is identical with applying this Remark to the case  $I = \emptyset$  of Remark 2).

## Acyclic inductive spectra of Fréchet spaces

by

JOCHEN WENGENROTH (Trier)

**Abstract.** We provide new characterizations of acyclic inductive spectra of Fréchet spaces which improve the classical theorem of Palamodov and Retakh. It turns out that acyclicity, sequential retracts (defined by Floret) and further strong regularity conditions (introduced e.g. by Bierstedt and Meise) are all equivalent. This solves a problem that was folklore since around 1970.

For inductive limits of Fréchet–Montel spaces we obtain even stronger results, in particular, Grothendieck’s problem whether regular (LF)-spaces are complete has a positive solution in this case and we show that even the weakest regularity conditions already imply acyclicity.

One of the main benefits from our results is an improvement in the theory of projective spectra of (DFM)-spaces. We prove the missing implication in a theorem of Vogt and thus obtain evaluable conditions for vanishing of the derived projective limit functor which have direct applications to classical problems of analysis like surjectivity of partial differential operators on various classes of ultradifferentiable functions (as was explained e.g. by Braun, Meise and Vogt).

**1. Introduction.** Given an inductive spectrum  $(E_n)_{n \in \mathbb{N}}$  of Fréchet spaces with inductive limit  $E = \text{ind}_n E_n$  Palamodov’s [21] definition of acyclicity can be rephrased as stating that the short exact sequence

$$0 \rightarrow \bigoplus E_n \xrightarrow{\sigma} \bigoplus E_n \xrightarrow{q} E \rightarrow 0$$

is topologically exact, where  $q((x_n)_{n \in \mathbb{N}}) = \sum x_n$  is the canonical quotient map and  $\sigma((x_n)_{n \in \mathbb{N}}) = (x_n - x_{n-1})_{n \in \mathbb{N}}$  ( $x_0 := 0$ ).

The origin of this definition is the subspace problem in (LF)-spaces (which itself is closely related to surjectivity problems in classical analysis): which subspaces of (LF)-spaces are again inductive limits of Fréchet spaces? Such subspaces are called limit subspaces and there exists a long list of papers dealing with this subject (see e.g. [13] and its list of references). The subspace problem arises in a natural way if one is concerned with the
