ON A COMPARISON PRINCIPLE FOR A QUASILINEAR ELLIPTIC BOUNDARY VALUE PROBLEM OF A NONMONOTONE TYPE

Abstract. A nonlinear elliptic partial differential equation with the Newton boundary conditions is examined. We prove that for greater data we get a greater weak solution. This is the so-called comparison principle. It is applied to a steady-state heat conduction problem in anisotropic magnetic cores of large transformers.

1. Introduction. Comparison and maximum principles are important features of second order elliptic equations that distinguish them from higher order equations and systems of equations. In this paper we deal with a quasilinear elliptic problem whose classical formulation reads:

\begin{align*}
\text{Find } u &\in C^1(\Omega) \text{ such that } u|_{\Omega} \in C^2(\Omega) \text{ and } \\
-\text{div}(A(\cdot, u) \text{ grad } u) &= f \quad \text{in } \Omega, \\
\alpha u + n^T A(\cdot, u) \text{ grad } u &= g \quad \text{on } \partial \Omega,
\end{align*}

where \( \Omega \subset \mathbb{R}^d, d \in \{1, 2, \ldots\} \), is a bounded domain with a Lipschitz continuous boundary, \( n = (n_1, \ldots, n_d)^T \) is the outward unit normal to \( \partial \Omega \), \( A = (a_{ij})_{i,j=1}^d \) is a uniformly positive definite matrix and \( \alpha \geq 0 \). Let the functions \( A, \alpha, f \) and \( g \) be sufficiently smooth for the time being (precise assumptions on these functions are given in Section 2).

The problem (1.1)–(1.2) describes a steady-state heat conduction in nonlinear inhomogeneous anisotropic media. The unknown function \( u \) represents the temperature, \( A \) is the matrix of heat conductivities, \( \alpha \) is the heat transfer coefficient, \( f \) is the density of volume heat sources and \( g \) is the density of surface heat sources. The existence and uniqueness of \( u \) is studied in [16] (and in [5, 6, 12, 13] for similar problems with other boundary conditions).

1991 Mathematics Subject Classification: Primary 35J60.

Key words and phrases: nonlinear boundary value problem, comparison principle, anisotropic heat conduction.
The main aim of this paper is to show the following comparison principle:

\[
(1.3) \quad f_1 \leq f_2 \& g_1 \leq g_2 \Rightarrow u_1 \leq u_2,
\]

where \( u_i \) is a weak solution of the problem (1.1)–(1.2) corresponding to the densities \( f_i \) and \( g_i \) of heat sources for \( i = 1, 2 \). Our method is completely different from that used in [5, 10, 23], where the classical solution \( u \in C^2(\Omega) \) is considered. Moreover, our assumptions on the matrix \( A(\cdot, u) \) are not covered by [5, 10, 23]. Note that the comparison principle (1.3) for linear problems (i.e., when \( A \) is independent of \( u \)) is a consequence of the weak maximum principle (see, e.g., [10, p. 32, 207]). For more information about maximum principles we refer to [21].

2. Weak formulation and existence. To state a weak formulation of problem (1.1)–(1.2) we assume that \( A = A(\cdot, \cdot) \) and \( \alpha = \alpha(\cdot) \) are bounded measurable functions,

\[
(2.1) \quad \text{ess sup}_{x, \xi, i, j} |a_{ij}(x, \xi)| \leq C, \quad \text{ess sup}_s |\alpha(s)| \leq C,
\]

where \( x \in \Omega, \xi \in \mathbb{R}^1, i, j \in \{1, \ldots, d\} \) and \( s \in \partial\Omega \). The components \( a_{ij} \) are assumed to be Lipschitz continuous with respect to the second variable, i.e., there exists \( C_L > 0 \) such that for all \( \zeta, \xi \in \mathbb{R}^1 \) and almost all \( x \in \Omega \) we have

\[
(2.2) \quad |a_{ij}(x, \zeta) - a_{ij}(x, \xi)| \leq C_L |\zeta - \xi|, \quad i, j = 1, \ldots, d.
\]

Further, let there exist \( C_0 > 0 \) such that for almost all \( x \in \Omega, \)

\[
(2.3) \quad C_0 \eta^T \eta \leq \eta^T A(x, \xi) \eta \quad \forall \xi \in \mathbb{R}^1 \forall \eta \in \mathbb{R}^d
\]

and let \( 0 \leq \alpha(s) \) for almost all \( s \in \partial\Omega \). To guarantee the existence of \( u \), we moreover assume that there exists a constant \( \alpha_0 > 0 \) and a nonempty relatively open subset \( \Gamma \subset \partial\Omega \) such that

\[
(2.4) \quad \alpha(s) \geq \alpha_0
\]

for almost all \( s \in \Gamma \). Recall that the boundary condition (1.2) is called the Newton boundary condition. It is called the Neumann boundary condition at those parts of \( \partial\Omega \) where \( \alpha = 0 \).

Finally, let \( f \in L^2(\Omega), g \in L^2(\partial\Omega) \) and \( V = H^1(\Omega) \), where \( H^1(\Omega) \) is the Sobolev space of functions whose first generalized derivatives belong to \( L^2(\Omega) \).

For simplicity, a possible dependence of \( A \) on \( x \) is not explicitly indicated in what follows. Set

\[
(2.5) \quad a(y; w, v) = (A(y) \text{ grad } w, \text{ grad } v)_{0, \Omega} + \langle \alpha w, v \rangle_{0, \partial\Omega}, \quad y, w, v \in V,
\]

\[
(2.6) \quad F(v) = (f, v)_{0, \Omega} + \langle g, v \rangle_{0, \partial\Omega}, \quad v \in V,
\]

where \( \langle \cdot, \cdot \rangle_{0, \Omega} \) and \( \langle \cdot, \cdot \rangle_{0, \partial\Omega} \) stand for the usual scalar products in \( L^2(\Omega) \) and \( L^2(\partial\Omega) \), respectively. Since \( A \) and \( \alpha \) are bounded by (2.1), we observe that
both the terms on the right hand side of (2.5) are finite, i.e., \( a(\cdot, \cdot, \cdot) \) is well
defined. Throughout the paper, the symbol \( \| \cdot \|_{k, \Omega} \) is used for the norm in
the product Sobolev space \( (H^k(\Omega))^q \) for \( k \in \{0, 1, \ldots\} \) and \( q \in \{1, 2, \ldots\} \).

Suppose that some \( u \) satisfy (1.1)–(1.2). Multiplying (1.1) by an arbi-
trary test function \( v \in V \) and then integrating over \( \Omega \), we arrive, by (1.2)
and the Green formula, at the following definition:

**Definition 2.1.** A function \( u \in V \) is said to be a **weak solution** of the
problem (1.1)–(1.2) if
\[
(2.7) \quad a(u; u, v) = F(v) \quad \forall v \in V.
\]

Next we present several remarks concerning the existence of the weak
solution.

**Remark 2.2.** The well-known Kirchhoff transformation (see [2, 9, 17]),
which changes the nonlinear problem to a linear one, can be applied in the
case of isotropic nonlinear media, i.e., when \( A \) is a scalar function. However,
it cannot be applied to prove the existence of \( u \) in the case of anisotropic
nonlinear media, in general. For instance, in examining a temperature field
in the magnetic circuit of a transformer (see Figure 3), nonlinear tempera-
ture dependencies of heat conductivities across and along lamination differ.
The associated \( 3 \times 3 \) matrix \( A \) of heat conductivities is diagonal and such
that \( a_{22} \neq a_{11} = a_{33} \). The temperature dependencies of the diagonal entries
differ in such a way that the types of nonlinearity in the \( x_1 \) and \( x_2 \) directions
are different (see [16]).

**Remark 2.3.** To prove the existence of a weak solution \( u \in V \) we cannot
apply the Minty–Browder theorem for monotone operators (cf. [9]), since our
problem does not in general lead to a monotone operator (see [13, p. 171]
for a one-dimensional example).

**Remark 2.4.** The problem of Definition 2.1 cannot be transform ed to
the minimization of some functional, since the associated operator \( A \) is not in
general a potential operator (see [12, p. 87] for a one-dimensional example).
The well-known symmetry conditions from [20, p. 41] are not satisfied.

**Remark 2.5.** We observe that there exists a constant \( C_0 > 0 \) such that
\[
(2.8) \quad C_0 \| v \|_{1, \Omega}^2 \leq a(y; v, v) \quad \forall y, v \in V.
\]
This inequality is a direct consequence of (2.3)–(2.5) and the following
**Friedrichs’ inequality** (see [19, p. 20]):
\[
\| v \|_{1, \Omega}^2 \leq C(\| \text{grad } v \|_{0, \Omega}^2 + \| v \|_{0, \Gamma}^2) \quad \forall v \in V.
\]
Using (2.5), (2.6), the boundedness of \( A, \alpha \) (see (2.1)) and the trace theorem
(see [19, p. 84]), it is not difficult to verify that
\[
(2.9) \quad | a(y; w, v) | \leq C \| w \|_{1, \Omega} \| v \|_{1, \Omega} \quad \forall y, w, v \in V,
\]
\[ |F(v)| \leq C \|v\|_{1,\Omega} \quad \forall v \in V. \]

**Theorem 2.6.** Let (2.1)–(2.4) hold. Then there exists a weak solution of the problem (1.1)–(1.2).

For the proof see [13]. The weak solution is obtained as a weak limit of Galerkin approximations. The proof is based on the properties (2.8)–(2.10), the well-known Brouwer theorem [8, 16] and the density theorem of [3].

**Remark 2.7.** From (2.8), (2.7), (2.6) and the trace theorem we have
\[ C_0 \|u\|_{1,\Omega}^2 \leq a(u;u,u) = (f,u)_{0,\Omega} + (g,u)_{0,\partial\Omega} \leq C(\|f\|_{0,\Omega} + \|g\|_{0,\partial\Omega})\|u\|_{1,\Omega}. \]

Hence, there exists a constant \( C > 0 \) (independent of the data \( f, g \)) such that
\[ \|u\|_{1,\Omega} \leq C(\|f\|_{0,\Omega} + \|g\|_{0,\partial\Omega}). \]

This means that we can estimate the norm \( \|u\|_{1,\Omega} \) by the “data”. We observe from (2.11) that for vanishing data the weak solution \( u \) is unique.

### 3. The comparison principle.

In this section we prove the uniqueness of \( u \) for any \( f \in L^2(\Omega) \) and \( g \in L^2(\partial\Omega) \). This result will be a consequence of the following comparison principle.

**Theorem 3.1.** Let (2.1)–(2.4) hold and let \( u_1, u_2 \in V \) be two weak solutions of the problem (2.7) corresponding to \( f_1, f_2 \in L^2(\Omega) \) and \( g_1, g_2 \in L^2(\partial\Omega) \), respectively. Assume that
\[ f_1 \geq f_2 \quad \text{a.e. in } \Omega \]
and
\[ g_1 \geq g_2 \quad \text{a.e. in } \partial\Omega. \]

Then \( u_1 \geq u_2 \) a.e. in \( \Omega \).

**Proof.** Let \( f_1 \geq f_2, g_1 \geq g_2 \) and let \( u_1, u_2 \) be the corresponding weak solutions. Put \( \Omega_0 = \{ x \in \Omega \mid u_1(x) < u_2(x) \} \) and assume, on the contrary, that
\[ \text{meas } \Omega_0 > 0. \]

Let \( \varepsilon > 0 \) be arbitrary and let us define (see Figure 1)
\[ \Omega_\varepsilon = \{ x \in \Omega_0 \mid u_2 - u_1 > \varepsilon \}, \]
\[ v_\varepsilon = \begin{cases} \min(\varepsilon, u_2 - u_1) & \text{in } \Omega_0, \\ 0 & \text{in } \mathbb{R}^d \setminus \Omega_0. \end{cases} \]

We show that \( v_\varepsilon \) can be applied in (2.7) as a test function. Since \( u_2 - u_1 \in V \), the positive part \( (u_2 - u_1)^+ \) also lies in \( V \). This is due to the fact that \( v \mapsto v^+ \) is a continuous mapping from \( H^1(\Omega) \) to \( H^1(\Omega) \) (see, e.g., [11,}
A comparison principle

The mapping \( v \mapsto |v| = v^+ + v^- \) is continuous as well. Therefore, the equality \( \min(a, b) = \frac{1}{2}(a + b - |a - b|) \) implies that

\[
(3.6) \quad v_\varepsilon = \min(\varepsilon, (u_2 - u_1)^+) \in V.
\]

Thus, by (2.7), we may write

\[
(3.7) \quad (A(u_i) \text{grad } u_i, \text{grad } v_\varepsilon)_{0, \Omega} + \langle \alpha u_i, v_\varepsilon \rangle_{0, \partial \Omega}
= (f_i, v_\varepsilon)_{0, \Omega} + \langle g_i, v_\varepsilon \rangle_{0, \partial \Omega}, \quad i = 1, 2.
\]

Since \( v_\varepsilon \geq 0 \) and \( \alpha \geq 0 \), we have, by (3.5),

\[
(3.8) \quad \alpha (u_1 - u_2) v_\varepsilon \leq 0 \quad \text{on } \partial \Omega.
\]

From (2.3), (3.5), (3.7), (3.8), (3.1) and (3.2) we obtain

\[
(3.9) \quad C_0 \|\text{grad } v_\varepsilon\|^2_{0, \Omega}
\leq (A(u_1) \text{grad } v_\varepsilon, \text{grad } v_\varepsilon)_{0, \Omega}
= (A(u_1) \text{grad } (u_2 - u_1), \text{grad } v_\varepsilon)_{0, \Omega \setminus \Omega_\varepsilon}
= (A(u_1) \text{grad } u_2 - A(u_1) \text{grad } u_1, \text{grad } v_\varepsilon)_{0, \Omega}
= (A(u_1) \text{grad } u_2 - A(u_2) \text{grad } u_2, \text{grad } v_\varepsilon)_{0, \Omega}
+ \langle \alpha (u_1 - u_2), v_\varepsilon \rangle_{0, \partial \Omega} + \langle f_2 - f_1, v_\varepsilon \rangle_{0, \Omega} + \langle g_2 - g_1, v_\varepsilon \rangle_{0, \partial \Omega}
\leq ((A(u_1) - A(u_2)) \text{grad } u_2, \text{grad } v_\varepsilon)_{0, \Omega}.
\]

The last scalar product can be further estimated by (3.4), (3.5), the Cauchy–Schwarz inequality and (2.2) as follows:
Combining (3.9) and (3.10), we obtain
\begin{equation}
\|\nabla v_\varepsilon\|_{0,\Omega} \leq \varepsilon C \|\nabla u_2\|_{0,\Omega_0 \setminus \Omega_\varepsilon}.
\end{equation}

According to (3.5) and (2.4),
\[
0 \leq v_\varepsilon \leq (u_2 - u_1)^+ = u_2 - u_1 \leq \frac{1}{\alpha_0} (\alpha u_2 - \alpha u_1) \quad \text{on} \quad \Gamma \cap \overline{\Omega}_0,
\]
and thus (since \(v_\varepsilon = 0\) on \(\Gamma \setminus \overline{\Omega}_0\))
\begin{equation}
v_\varepsilon^2 \leq \frac{1}{\alpha_0} (\alpha u_2 - \alpha u_1) v_\varepsilon \quad \text{on} \quad \Gamma.
\end{equation}

Moreover, by (3.9),
\[
-\langle \alpha u_1 - \alpha u_2, v_\varepsilon \rangle_{0,\partial \Omega} + C_0 \|\nabla v_\varepsilon\|^2_{0,\Omega} \leq \langle (A(u_1) - A(u_2)) \nabla u_2, \nabla v_\varepsilon \rangle_{0,\Omega}.
\]

Consequently, Friedrichs’ inequality, (3.12), (3.10) and (3.11) imply that
\[
\|v_\varepsilon\|^2_{0,\Omega} \leq C_1 (\|v_\varepsilon\|^2_{0,\Gamma} + \|\nabla v_\varepsilon\|^2_{0,\Omega})
\leq C_2 (\langle \alpha u_2 - \alpha u_1, v_\varepsilon \rangle_{0,\partial \Omega} + \|\nabla v_\varepsilon\|^2_{0,\Omega})
\leq C_3 (\langle \alpha u_2 - \alpha u_1, v_\varepsilon \rangle_{0,\partial \Omega} + C_0 \|\nabla v_\varepsilon\|^2_{0,\Omega})
\leq C_3 (\langle (A(u_1) - A(u_2)) \nabla u_2, \nabla v_\varepsilon \rangle_{0,\Omega})
\leq \varepsilon C_4 \|\nabla u_2\|_{0,\Omega_0 \setminus \Omega_\varepsilon} \|\nabla v_\varepsilon\|_{0,\Omega_0 \setminus \Omega_\varepsilon}
\leq \varepsilon^2 C_5 \|\nabla u_2\|^2_{0,\Omega_0 \setminus \Omega_\varepsilon}.
\]

From this, (3.5), the facts that \(u_2\) is fixed and \(\Omega_\varepsilon \subset \Omega_0\), we arrive at
\[
\text{meas } \Omega_\varepsilon = \varepsilon^{-2} \int_{\Omega_\varepsilon} \varepsilon^2 \, dx \leq \varepsilon^{-2} \|v_\varepsilon\|^2_{0,\Omega}
\leq C_5 \|\nabla u_2\|^2_{0,\Omega_0 \setminus \Omega_\varepsilon} \to 0 \quad \text{as} \quad \varepsilon \to 0,
\]
where \(C_5 > 0\) is independent of \(\varepsilon\). This, however, contradicts (3.3) and (3.4), since \(\text{meas } \Omega_\varepsilon \to \text{meas } \Omega_0\). Consequently, \(\text{meas } \Omega_0 = 0\) and \(u_1 \geq u_2\) a.e. in \(\Omega\).

**Corollary 3.2.** Let (2.1)–(2.4) hold. Then there exists at most one weak solution of the problem (1.1)–(1.2).

**Proof.** According to Theorem 3.1 we have \(u_1 \geq u_2\) and \(u_1 \leq u_2\) for \(f_1 = f_2\) and \(g_1 = g_2\). This proves the uniqueness of the weak solution \(u\).
Remark 3.3. Theorem 3.1 and its proof can be easily modified for Dirichlet boundary conditions or mixed Dirichlet–Newton boundary conditions. A proof of the uniqueness of the classical solution of the problem (1.1)–(1.2) is given in [5] for the Dirichlet boundary conditions and in [12] for mixed conditions. The uniqueness of the weak solution for the mixed nonlinear boundary conditions is proved also in [13] without application of the comparison principle. Other uniqueness theorems for general nonlinear problems with Dirichlet boundary conditions are given in [1, 14].

Remark 3.4. There exist examples of nonunique solutions if the elliptic equation is not in the divergence form (see, e.g., [10, p. 209], [18, p. 178]). We can also get nonunique solutions of our divergence form problem (1.1)–(1.2) if the condition (2.2) is violated. To see this, we recall the following example due to J. Malý. Let \( d = 1, \Omega = (0,1) \) and consider two fixed real smooth functions \( u_1, u_2 \) such that \( u_1 < u_2 \) on \((0,1), u_1(0) = u_2(0), u_1'(0) = u_2'(0), u_1(1) = u_2(1), u_1'(1) = u_2'(1), u_1' \geq 1 \) and \( u_2' \geq 1 \) (see Figure 2).

Let us define a real function \( A \) on the graphs of \( u_1 \) and \( u_2 \) as follows:

\[
A(x, \xi) = \frac{1}{u_i'(x)} \text{ for } x \in [0,1], \xi = u_i(x), i = 1, 2.
\]

Then by Tietze's extension theorem (see, e.g., [22, p. 422]) there exists a continuous extension (still denoted by \( A \)) so that \( A(\cdot, \cdot): \Omega \times \mathbb{R}^1 \rightarrow \mathbb{R}^1 \) and (2.1) and (2.3) hold. We see that

\[
-(A(x, u_i)u_i')' = 0 \text{ for } i = 1, 2,
\]

i.e., \( u_1 \) and \( u_2 \) are solutions of (1.1) with \( f = 0 \) and the Newton boundary conditions (1.2) for \( \alpha = 1 \) and \( g = 0 \). However, in this case it is not difficult
to check that $A$ is not Lipschitz continuous (with respect to the second variable) near those points where $u_1$ and $u_2$ bifurcate. The condition (2.2) is thus essential to get the uniqueness.

Another one-dimensional example of nonunique solutions of a nonlinear elliptic boundary value problem is given in [1, p. 1163].

4. An application. A steady-state heat conduction problem defined by (1.1)–(1.2) describes a temperature distribution in large transformers. Their magnetic cores (consisting of iron sheets) are nonlinear orthotropic media the heat conductivities of which can be represented by a diagonal matrix $A = A(u)$. The temperature dependencies of the heat conductivity coefficients $a_{11}(u)$ and $a_{22}(u)$ across and along the lamination, respectively, differ substantially (see Remark 2.2).

Due to the symmetry of the magnetic core (see Figure 3), we can solve the problem (1.1)–(1.2) on a smaller domain, which will be denoted by $\Omega$.

![Fig. 3](image)

We prescribe the homogeneous Neumann boundary conditions (i.e. $\alpha = 0$ in (1.2)) at those parts of $\partial\Omega$ which correspond to planes of symmetry, and let $\alpha \geq \alpha_0 > 0$ be the heat transfer coefficient on the remaining part $\Gamma$ of the boundary $\partial\Omega$. This means that $\Gamma$ is that part of the boundary $\partial\Omega$ which is cooled by oil and $\partial\Omega \setminus \Gamma$ corresponds to all planes of symmetry.
We have $g = \alpha u_0$ on $\Gamma$ (cf. (1.2)), where $u_0$ is the temperature of cooling oil, and $g = 0$ on $\partial \Omega \setminus \Gamma$. The density $f$ of volume heat sources is positive due to the alternating electromagnetic field.

Note that the knowledge of the temperature distribution is very important to avoid a local overheating. If the temperature exceeds prescribed limits, the cooling oil starts to boil which may cause destruction of the whole transformer. The comparison principle yields a natural assertion: Any rise of the density of heat sources always causes that the temperature will not decrease at any point. This confirms that the nonlinear mathematical model (1.1)–(1.2) of heat conduction has reasonable properties.

**Remark 4.1.** We have $\alpha = 0$ on $\partial \Omega \setminus \Gamma$. Setting $v = 1$, we see by (2.5), Definition 2.1 and (2.6) that

$$\int_{\Gamma} \alpha u \, ds = \int_{\partial \Omega} \alpha u \, ds = a(u; u, 1) = F(1) = (f, 1)_{0, \Omega} + \langle g, 1 \rangle_{0, \partial \Omega}$$

$$= \int_{\Omega} f \, dx + \int_{\Gamma} \alpha u_0 \, ds.$$ 

Hence we observe an interesting fact that the average surface temperature rise $\vartheta_{\Gamma}$ on $\Gamma$ does not depend upon the type of nonlinearity of the heat conduction coefficients,

$$\vartheta_{\Gamma} \equiv \frac{1}{\text{meas} \Gamma} \int_{\Gamma} (u - u_0) \, ds = \frac{1}{\alpha|\Gamma| \text{meas} \Gamma} \int_{\Omega} f \, dx,$$

provided $\alpha|\Gamma$ is constant.

Note that the total temperature flux on $\Gamma$ is also independent of the heat conduction coefficients (which follows from the Green theorem).

**Remark 4.2.** Numerical realization of the problem (1.1)–(1.2) can be obtained by the finite element method. The questions of the existence, uniqueness and convergence of discrete solutions are studied in [4, 13]. A discrete maximum principle is derived in [15]. For approximation of the curved boundary and numerical integration, see [6, 7, 24]. According to numerical tests [16], the hottest place of the magnetic core is in concave angles of the L- and T-joints (see Figure 3).

**Acknowledgements.** The authors wish to thank Prof. R. B. Kellogg of the University of Maryland for fruitful discussions and M. Lehtinen of the University of Jyväskylä for his help in carrying out the figures. The work was supported by grant No. A1019601 of the Grant Agency of the Academy of Sciences of the Czech Republic.
